# INDEX

- ABDOMINAL Structures of Possible Epigenetic Function in the Diptera:** Glandulae (K. G. V. Smith and R. G. Davies), 321
- Abe, S., and Yasuura, J.:** Magnetic Resonance Investigation of the Runey Nickel Catalyst, 1192
- Aberdeen University of:** Appointments, 469
- Chair of Medical Physics,** 1336
- Aberdeenshire Granite and Gabbro:** Potassium-Argon Ages of some (Dr. P. E. Brown et al.), 1287
- Abnormal Haemoglobins and the Genetic Code** (D. Beale and Dr. H. Lehmann), 259
- ABO:** Localization of Haptoglobin and (T. W. J. Huethinx et al.), 327
- Abooy, D. A., and Andrade, Prof. E. N. da C.:** Distribution of Grain Size in Annealed Metals, 68
- Abraham, Dr. A., et al.:** Reproduction of the Viruses Isolated from Cases of Infectious Hepatitis on Detroit-6(VA) Cell Line, 326
- Absence of Antibody Production in the Burns of Fabricius** (Dr. P. B. Dent and Dr. R. A. Good), 491
- Absorbing Species in Carbonyl Sulphide Discharge Products:** Identification of Disulphur Monoxide as an (R. Engleman, Jun.), 1386
- Absorption in Man:** Mechanism of Inositol (L. McColl and Dr. J. A. Nisbets), 949
- Absorption:** Relation of Magnesium Ions to Calcium and Phosphate (Prof. I. Clark), 982
- Absorption Spectra of Haemoglobins from Various Vertebrates:** Ultra-Violet (Prof. F. Jung et al.), 990
- Abstracts:** Science, 1243
- Academician Nikolai Vavilov Prize, Award by the Soviet Academy of Sciences,** 690
- Accelerated Deformation of Rock Salt at Elevated Temperature** (T. F. Loomnick and R. L. Bradshaw), 158
- Acetabularia crassifolia:** Effects of Red and Blue Light on the Growth and Morphogenesis of (Dr. J. Tarborgh), 1360
- [<sup>3</sup>H] Acetate in Rumex Field:** Loss of Methyl Tricardium from (R. A. Leag and G. J. Leonard), 760
- Acetylcholine, Choline and Betaine Churns in Aqueous Solution:** Relations between (Dr. F. G. Canepa), 1152
- Acetylcholine:** Conformation of (Dr. F. G. Canepa and Dr. E. F. Mooney), 78
- Acetylcholine from a Nerve Terminal by Electric Pulses of Variable Strength and Duration:** Release of (Prof. B. Katz and Prof. R. Miledi), 1097
- Acetylcholine in the Electric Organ of Torpedo** (Dr. D. Morris, G. Ball and Dr. C. O. Hebb), 1295
- Acetylcholine on Cochlear Responses:** Action of (Y. Katsuki, Y. Tanaka and T. Miyoshi), 32
- Acetylcholine Release from the Cerebral and Cerebellar Cortex:** Its Role in Cortical Arousal (Dr. J. W. Phillips and G. C. Chong), 1253
- N-Acetylserine Nucleoside Digestion by Human Oral Bacteria** (S. M. Amir, Dr. S. A. Barker and S. A. Woodbury), 979
- N-Acetylserine Nucleoside Lyase from Rat Granulation Tissue:** Time-Course Concentration of (Dr. A. P. Miskin et al.), 875
- Achoeridia Fragmenta:** Newly Discovered Mesozoic fossils containing (Dr. G. J. H. McCall and W. H. Cleverly), 851
- Acid Nucleases of the Bovine Adrenal Medulla** (A. D. Smith and Dr. H. Winkler), 634
- Actinically-Induced Loss of Kinesthetically Deoxyribonucleic Acid in Crithidia fasciculata (Culex pipiens Scutellum)** (Prof. H. N. Guttman and R. N. Eisenman), 1280
- Actinomycin D in vivo:** Inhibition of Adrenocortical Responses to ACTH by (Prof. J. Vamlikos-Danellis and M. Hall), 766
- Actinomycin D:** Effect of, on the Inactivity of Trypanosoma cruzi (Dr. J. F. Fernandes, M. Halciano and O. Cascaelli), 1004
- Actinomycin D on Uterine Stimulation by Oestrogen:** Participation of Adrenocortical Hyperactivity in the Suppressive Effect of Systemic (Barbara M. Lippe and Prof. Clara M. Szego), 272
- Action of Neuroleptic Drugs:** The (Prof. Hans-J. Haase and Paul A. J. Janssen), review by D. F. Skarman, 232
- Actions of Hormones on Molecular Processes,** (edited by G. Litwack and D. Kritchevsky), review by Dr. A. Kornet, 678
- Activation Analysis** (Dr. J. M. A. Lenihan), 347
- Activity of Nicotine and Inactivity of Kallikrein and Kallidin in Aggregation of Blood Platelets** (Prof. E. Werle and H. Schuevalbern), 871
- Activity of Roots of Grass Swards:** Tracer Technique used in Examination of (M. J. D'Aoust and R. S. Taylor), 893
- Actomyosin and Myosin of Vascular Smooth Muscle** (Dr. M. L. Mallin), 1297
- Actos, Dr. L. W.:** Contribution of Characteristic X-rays to the Reduction of Solar Flares, 737
- Adamantine Semiconductors:** Quaternary (Dr. B. R. Pampin and J. S. Shah), 180
- Adams, D. J., et al.:** A Search for Low-energy Gamma-rays from the Quasar 3C286, 396
- Adams, J. F., et al.:** Vitamin B<sub>12</sub> Analogues in Non-legume Root Nodules, 319
- Adaptation of Rat Liver Cytochrome to DL-Ethionine and to Thyrotoxicity:** Effects of Pyridoxine Deficiency on the (F. Chetagner and O. Durren-Treutmann), 1390
- Adaptation to the Environment:** Section 4 of the Handbook of Physiology (edited by D. B. Dill et al.), review by Dr. J. Bligh, 1324
- Addink, Dr. N. W. H.:** Agreement between Carcinoma Experiments in vivo and Low-energy X-ray Irradiation of the Metalloprotein Carbonyl Anhydride, 1271
- Addis Ababa:** Comparison of the Diurnal Variation of the Horizontal Component of the Earth's Magnetic Field at Nairobi with that at (Prof. A. N. Hunter and R. Dool), 970
- Adrenaline Nucleosides on Porphyrin Synthesis by Rhodospirillum rubrum:** Mechanism of the Inhibitory Effect of (A. Galdos and M. Galdos-Torbk), 640
- Adenosine Diphosphate and Adrenaline on Mean Platelet Shape:** Effects of (Dr. J. R. O'Brien), 306
- Adenosine Diphosphate-Induced Platelet Aggregation by Histamine:** Inhibition of (Dr. J. W. Conestantine), 91
- Adenosine Monophosphate Changes in Rat Heart following Ephedrine Administration:** Kinetics of Cyclic (W. Y. Cheung and Dr. J. R. Williamson), 979
- Adenosine 3',5'-Monophosphate in vivo:** Cardiovascular and Metabolic Effects of (Dr. R. A. Levine and Dr. J. A. Vogel), 987
- Adenosine Triphosphatase Activity of Isolated Cellular Fractions:** Effect of Cardiolipin on the (J. Hradec), 982
- Adenosine Triphosphate and Muscular Contraction and Relaxation** (Prof. J. Singh), 1300
- Adenovirus Haemagglutinin of Group 2:** Serological Relationship between (Prof. R. Wignall et al.), 1207
- Adipose Tissue:** Effect of Alloxan-Diabetes on the Activity of Citrate Cleavage Enzymes in (Prof. J. Brown and Patricia McLean), 407
- Adler, R., Berzin, M., and Schiffer, M.:** Introduction to General Relativity, review by Dr. C. W. Kilmister, 793
- Adolph, E. F., et al. (edited by):** Handbook of Physiology, Section 4, Adaptation to the Environment, review by Dr. I. B. Begg, 1324
- Adrenal Damage and Cancer with Metabolites of 7,12-Dimethylbenz(a)anthracene:** Induction of (Prof. E. Boyland et al.), 816
- Adrenal Gland:** Alternative Pathway of Androgen Biosynthesis in the Human (Dr. G. L. Cohn), 297
- Adrenal Gland of the Rat:** Direct Action of Adrenocorticotrophic Hormone on Lipase in the (M. Palkovik et al.), 636
- Adrenal Medulla (Bovina):** Acid Nucleases of the (A. D. Smith and Dr. H. Winkler), 634
- Adrenal Medulla in the Hibernation of the 13-Lined Ground Squirrel:** non-essential Role of the (Dr. R. A. Hoffman and Dr. R. J. Hester), 656
- Adrenal Mitochondria by Cyclic 3',5'-Adenosine Monophosphate:** Stimulation of Steroid C-11 $\beta$  Hydroxylation in (Prof. S. Roberts et al.), 188
- Adrenal Steroids and Disease** (C. L. Cope), review by Dr. M. Vogt, 1224
- Adrenaline on Mean Platelet Shape:** Effects of Adenosine Diphosphate and (Dr. J. R. O'Brien), 306
- Adrenocortical Hyperactivity in the Suppressive Effect of Systemic Actinomycin D on Uterine Stimulation by Oestrogen:** Participation of (Barbara M. Lippe and Prof. Clara M. Szego), 272
- Adrenocortical Responsiveness to ACTH by Actinomycin D in vivo:** Inhibition of (Prof. J. Vamlikos-Danellis and M. Hall), 766
- ACTH by Actinomycin D in vivo:** Inhibition of Adrenocortical Responsiveness to (Prof. J. Vamlikos-Danellis and M. Hall), 766
- Adrenocorticotrophic Hormone on Lipase in the Adrenal Gland of the Rat:** Direct Action of (M. Palkovik, L. Macho and B. Moeniger), 636
- ACTH Peptides, in vivo and in vitro:** Melanocyte-stimulating Hormone Activity of Synthetic MSH and (Dr. A. J. Kardin et al.), 978
- Advances in Knowledge of a Fossil Fern,** 1337
- Advances in Chemical Engineering, Volume 5** (edited by Thomas B. Drew et al.), review by Prof. J. F. Richardson, 231
- Advances in Genetics, Volume 12** (edited by E. W. Casper and J. M. Thoday), review by Prof. C. H. Waddington, 227
- Advances in Gerontology: Research,** (edited by B. L. Strahler), Vol. 1, review by Prof. P. L. Krohn, 676
- Advances in Petroleum Chemistry and Refining, Volume 9** (edited by John J. McKetta, Jun.), review by H. B. Milner, 230
- Advantages resulting from the Addition of a Versatile Multichannel Analyser to an Electron Spin Resonance Spectrometer** (M. Kent and Dr. J. R. Malford), 1193
- Advisory Committee for Scientific and Technical Information,** 353
- Aedes aegypti Eggs:** Hatching Pattern of (Dr. M. S. Quraishi), 882
- Aeronautical Problems:** Current (edited by J. Schijve, J. R. Heath-Smith and E. R. Walbourne), review by B. N. Cole, 342
- Affairs:** Biology and Horace, 1338
- Aflatoxin:** Induction of Chromosome Aberrations by (Dr. Lorna J. Lilly), 433
- Africa (West):** Upper Cretaceous Fossil Molluscs in South America and (Prof. R. A. Reymond), 1384
- African Elephants:** Haemoglobins of Adult and Foetal (Dr. E. Kjelhauser et al.), 424
- Age, Effects of, on the Recall of Dichotic Words** (Prof. W. K. Caud), 109
- Age:** Changes in the Quantity and Nature of Collagen in Rabbit Skin as a Function of (Dr. M. E. Nimol et al.), 865
- Age of the New Red Sandstone in South Devonshire,** (Prof. D. J. C. Laming), 624
- Age of the Serra Geral Formation:** Radiometric (Dr. K. M. Creer et al.), 282
- Age of Wireless:** The Golden Age (Am. Briggs), review by T. H. Hawkins, 447
- Age of Rocks from Jan Mayen and an Outline of its Volcanic History:** Potassium-Argon (P. J. Fitch et al.), 1349
- Ages of Some Aberdeenshire Granite and Gabbro:** Potassium-Argon (Dr. P. E. Brown et al.), 1287
- Agglutination of Bull Spermatozoa by Phytoagglutinin present in Soy-beans:** Tail to Tail (Prof. T. Keshivabara et al.), 831
- Agglutinating Antibodies in Allergic Encephalomyelitis:** Effect of Treatment with 2-mercaptoethanol on Tanned Red Cell (E. A. Caspary and E. Janet Bell), 1305
- Agglutinating Antibodies to Listeria monocytogenes among Vertebrates:** Distribution of (Prof. John W. Osobold), 209
- Aghon-Pret, D.:** Floral Meristem-organizing Gradient in Tobacco Stems, 1211
- (Agnatha):** Brain of the Heterostracod (Dr. P. Whitting and Dr. L. B. H. Tarlo), 829
- Agol, V. L., and Maslova, S. V.:** Genetic and Non-genetic Factors in Chromatographic Behaviour of Poliovirus, 1005
- Agrell, Prof. I. P. S., and Christensen, E. G.:** Changes of Histone Composition in the Developing Chick Embryo, 638
- Aikens, D. A., and Morris, Prof. M. L.:** Synthesis of Tri-(hexafluoroacetylacetonato)-Chromium(III), 631
- Airborne Observations of Natural Radioactivity in the Atmosphere** (J. A. Warburton et al.), 181
- Aircraft and Missiles:** Rain damage in (Dr. J. H. Brunton et al.), 925

- Alley, P. L., and Dalton, Prof. F. S.: Primary Processes of Photo-oxidation of Aqueous Fe(II) Species, 1190
- Alkamatz, Hideo and Kinosita, Minoru: Electron Spin Resonance Absorption of Solid Ion-radical Salt of  $N,N,N',N'$ -Tetraethyl-p-phenylenediamine and 7,7,8,8-Tetra-p-quinoxaline, 291
- Akhizer, Prof. N. J.: Classical Moment Problem, review by Prof. T. A. Broadbent, 1117
- Aksenova, N. N., et al.: Effect of Ribonuclease on Anti-Tumour Activity of Ribonucleic Acid from Normal Tissues, 40
- Albon, N., and Packard, A.: Habit of Triglyceride Crystals, 1098
- Albright and Wilson Group: The, 355
- Albumin Variants in Man: Paucity of (Dr. B. L. Cohen), 1109
- Album, Dr. H. E. and Grant, Dr. N. H.: Peptide Hydrates: Influence of the Hydration State on the Properties of  $\alpha$ -Aminobenzylpenicillin, 645
- Alcohol Dehydrogenase: Dehydrogenation of trans-trans Farnesol by Horse Liver (G. R. Walker), 1389
- Aldehydes of Seroprotease Activation of Plasminogen: Selective Inhibition by (L. Staphans and Dr. F. B. Taylor, jun.), 754
- 'Alderlin' (Pronothal) In Mice: Carcinogenicity of (Dr. R. Howe), 594
- Alder Root-nodule Tissue containing the Endophyte: *In vitro* Cultivation of (Dr. J. H. Becking), 885
- Alderson, Dr. T.: Chemically Induced Delayed Germinal Mutation In *Drosophila*, 164
- Aldosterone of Active Sodium Transport by the Isolated Colon of the Toad, *Bufo marinus*: Stimulation by (G. Coffé and Dr. J. Crabbe), 1299
- Aldred, C.: Egypt to the End of the Old Kingdom, review by M. C. Burkitt, 1326
- Alexander, Dr. R. A.: Obituary by Dr. B. C. Jensen, 1032
- Algae after a Period of Darkness: Restoration of Irradiated (Elena Marzenko), 542
- Algae: Chlorophyll Inhibition of the Growth of Green (Dr. F. J. Taylor), 783
- Algae: Chromatic Adaptation in Benthic Marine (R. N. Cross et al.), 547
- Alkali Azides: Chemiluminescence and Chemi-electron Emission from (G. D. Singer and Dr. H. J. Meiler), 1073
- Alkali Basaltic Magmas: Differentiation of (M. K. Bose), 1187
- Alkali Imidodiphosphates: Structural Differences between the (Dr. D. W. Jones et al.), 186
- Alkaline Phosphatase Activity: Effect of Magnesium Deficiency on Plasma (Dr. F. W. Heston), 1292
- Alkaline Phosphatase Polymorphism of the Human Placenta: Genetics of the (Dr. E. B. Robson and Prof. H. Harris), 1257
- Alkaloids: Stimulation of Heart Cell Production in Lymph Nodes of the Rat by Pyrrolizidine (Dr. E. Diener and Prof. A. T. Dick), 1305
- Alkales for  $\beta$ -Chain: Haemoglobin-binding Sites and Presence of Additional (Prof. B.-S. Solin et al.), 1264
- Allen, Dr. G.: Appointment to Chair of Chemical Physics at University of Manchester, 688
- Allergic Activity: Chlorogenic Acid: Further Evidence for its Antigenic and (D. S. Barlett et al.), 1155
- 'Allergic' Encephalomyelitis: Anti-carboxylic Antibodies in Cerebrospinal Fluid of Rabbits with Experimental (Dr. E. Kuvart and Dr. B. Nledleck), 991
- Allergic Encephalomyelitis: Effect of Treatment with 2-Mercaptoethanol on Tanned Red Cell Agglutinating Antibodies in (E. A. Campary and E. Janet Bell), 1305
- 'Allergic' Encephalomyelitis with Anti-brain Serum Injected into the Latent Ventricle of the Brain: Passive Transfer of (Prof. B. D. Janovik et al.), 428
- Alling, Dr. D. W., et al.: Serological Relationship between Adenovirus Haemagglutinins of Group 2, 1207
- Allison, Dr. A. C., and Paton, Miss G. R.: Chromosome Damage in Human Diploid Cells following Activation of Lysosomal Enzymes, 1170
- Allison, J. B., and Munro, H. N. (edited by): Mammalian Protein Metabolism, review by Prof. D. C. Harriman, 117
- Allogeneic and Xenogeneic Tissue Culture Cells: PHA-Induced Cytotoxic Action of Unsensitized Immunologically Competent Cells on (Dr. G. Holm and Prof. P. Perlmann), 818
- Alloxan-Diabetes on the Activity of Citrate Cleavage Enzyme in Adipose Tissue: Effect of (Prof. J. Brown and Patricia McLean), 407
- Alloy of Aluminium, Zinc and Magnesium: Effects of Silver and Two-step Aging Treatments on a Weldable (Dr. K. G. Kent), 182
- Alloys: Theory of Order-Disorder in (M. A. Krivogor and A. Smirnov), review by J. A. Cottrell, 1023
- Amik, Dr. Sumner, et al.: Reproduction of the Viruses Isolated from Cases of Infectious Hepatitis on Detroit-6(VA) Cell Line, 326
- Alpha-globulin Component Absent in Serum of Human Forsters (M. Jirica), 98
- Alpha Rhythm and the Orientation of the Eyes: An Unexpected Artefact in the Human Electroencephalogram concerning the (Dr. T. Mufibolland and Dr. C. R. Evans), 36
- Alstonia constricta F. Muell.: Reserpine in a Tissue Culture of (Prof. D. P. Carew), 89
- Altered Cardiac Regulation of Exogenous Noradrenaline produced by Stress in Young Rabbits (Prof. C. N. Gillie), 1302
- Alternative Pathway of Androgen Biosynthesis in the Human Adrenal Gland (Dr. G. L. Cohn), 297
- Altitude and Athletic Performance (Dr. L. G. C. E. Pugh), 1397
- Altitude: 'Unicomycin' Treatment of Staphylococcal Infection at High (Dr. R. Ehrlich and B. J. Meisner), 1109
- Altitude (12,470 ft., 3,800 m): Spinal Cord Convulsions in the Developing Rat at (Prof. Louise M. Helm), 299
- Altland, H. W., and Weber, Dr. U.: Red Pigments of *Dactylosaurus rubicundus* and *D. arbusculus* (Hemiptera, Aphididae), 1295
- Altman, Prof. J., and Dias, Dr. G. D.: Post-natal Origin of Microneurons in the Rat Brain, 953
- Altman, P. P., and Chayen, J.: Retention of Nitrogenous Material in Unfixed Sections during Incubation for Histochemical Demonstration of Enzymes, 1205
- Aluminium in Steam-sterilized Soils: Extractable (J. H. L. Meeking), 439
- Al-Fe Isomorphous Substitution in  $3\text{CaO}\cdot\text{Al}_2\text{O}_3$  and  $2\text{CaO}\cdot\text{Fe}_2\text{O}_3$ , and Interactions between the so-called CaA and CaF Phases (Dr. P. Tarte), 973
- Aluminium-Magnesium-Silver System: Evidence for a Ternary Phase in the (M. J. Wheeler et al.), 746
- Aluminium Nitride Whiskers: Strength of (Dr. T. J. Davies and Dr. P. E. Evans), 254
- Aluminium Single Crystals: Orientation-dependence of Fatigue-accelerated Creep in (Prof. A. J. Kennedy and N. C. McGill), 1086
- Aluminium, Zinc and Magnesium: Effects of Silver and Two-step Aging Treatments on a Weldable Alloy of (Dr. K. G. Kent), 182
- Avarenga Price, 1965, Awarded to Dr. H. F. Harlow, 692
- Avarez, Dr. R. Z.: Obituary by Dr. I. Gordon, 806
- Awmy, C. D., et al.: Blood Levels of Drugs at the Equilibrium State after Multiple Dosing, 1301
- Amano, E., et al.: Genetic Recombination with Ethyl-mechanophosphate-Induced Virus Mutants in Mice, 890
- Ambrose, E. J., et al.: A Highly Selective Cardiolitic Agent Isolated from *Cobra* Venom, 534
- America (North): Noctilucent Clouds over (B. Fogie), 696
- America (South) and West Africa: Upper Cretaceous Fossil Molluscs In (Prof. R. A. Reymont), 1384
- American Geophysical Union: Fifth Western National Meeting of the, 469
- American Museum of Natural History, Bulletin of the, 22
- American Oyster (Dr. C. M. Yonge), 1138
- American Philosophical Society: The, 468
- Amines: A Common Mode of Antiviral Action for Ammonium Ions and Various (R. D. Fletcher et al.), 664
- Amines in Man: Significance of Smoking in Investigations of Urinary Excretion Rates of (Prof. A. H. Beckett et al.), 200
- Amines in the Urine of Schizophrenics: Phenolic and Indole (M. Takeeda et al.), 1199
- Amino-acids and Peptide Bonds with Formaldehyde as measured by Changes in the Ultra-violet Spectra (Prof. L. J. Saldé et al.), 169
- Amino-acids and Peptides in Human Gastric Juice with Particular Reference to Pernicious Anaemia: A Review (Dr. J. G. Heathcote and R. J. Washington), 941
- Amino-acids: Coding of Polar and Non-polar (Prof. M. V. Volkenstein), 294
- Amino-acids: Correlation between Coding-Triplets and (Dr. S. R. Pele), 597
- Amino-acids on Human Fingers: The question of Contamination in Microanalysis: Free (Prof. J. Oró and H. B. Skowes), 1042
- Amino-acids on Protein-synthesizing Activity of Isolated Ribosomes: Influence of Alterations in Intracellular Levels of (Dr. B. M. Hankins and Prof. S. Roberts), 862
- $\alpha$ -Aminobenzylpenicillin: Peptide Hydrates: Influence of the Hydration State on the Properties of (Dr. N. H. Grant and Dr. H. E. Albura), 645
- 2-Aminobenzylphosphonic Acid from Bovine Brain: Isolation and Identification of (H. Shimizu, Y. Kakimoto, T. Nakajima, A. Kanazawa and I. Sano), 1197
- 4-Aminoimidazole-5-carboxamide: Effect of Halidine on the Urinary Excretion of (J. E. Middleton et al.), 310
- Azurophilic: Existence of Half-salt Cations in Aqueous Solutions of (Dr. G. Chichani et al.), 1385
- Amir, S. M., Barker, Dr. S. A. and Woodbury, S. A.: N-Acetylmannosamine Digestion by Human Oral Bacteria, 979
- Ammonium Ions and Various Amines: A Common Mode of Antiviral Action for (R. D. Fletcher et al.), 664
- Amory, Viscount, appointed to the Medical Research Council, 23
- Amphibian Embryo: Synthesis of Ribonucleic Acid by Different Regions of the Early (Prof. C. H. Waddington and Mrs. E. Parkowska), 1244
- Amphibian Metamorphosis: Turnover of Nuclear and Cytoplasmic Ribonucleic Acid at the Onset of Induced (Dr. J. R. Tata), 378
- Anaemia: Amino-acids and Peptides in Human Gastric Juice with Particular Reference to Pernicious (Dr. J. G. Heathcote and R. J. Washington), 941
- Anaerobic Glycolysis of the Regenerating Rat Liver: Crude Effect and the (Dr. E. Clerf and Dr. P. Ciccarone), 762
- Anaerobic Oxidation of Glucose by the Cell-free Extract from Vegetative Cells of *S. aureus*: Inhibitory Effect of Dipicolinic Acid on the (Yoshio Hachisaka et al.), 220
- Anaesthesia and Temperature Effect Mechanism in Neuromuscular Blocking by  $\text{N}^+$  Quaternary Depolarizing Drugs (Dr. F. G. Canepa), 1149
- Anaesthetics: Inhibition of Brain Processes by General (Prof. G. Ungar), 419
- Analysar for Tape-recorded Signals: An Automatic Dynamic Spectrum (Dr. R. L. Dowden and M. W. Emery), 493
- Analysis and Planning of Management, 810
- Analysis of Networks: Tensor (Dr. G. Kron), review by Dr. W. J. Gibbs, 1118
- Analysis of Queuing and Renewal within Human Systems (Prof. J. H. Franzer), 1139
- Analytical Chemistry of Molybdenum (A. I. Bussey), review by Dr. B. J. Dixon, 8
- Anand, S. P. S.: Magnetoacoustic Energy and Stability of Supermassive Stars, 1345
- Anbar, Ma et al.: Oxidase-like Activity of the Copper (II) Poly-L-histidine Complex, 1386
- Andersen, C. A., and Kell, K.: Occurrences of Stibolite,  $\text{Sb}_2\text{O}_3$ , in Meteorites, 745
- Andersen, S. B.: Metabolism of Human Gamma Globulin, review by Dr. S. Cohen, 1116
- Anderson, Dr. A. J.: Effect of Anionic Polyelectrolytes on the Formation and Composition of Plasma Euglobulins, 408
- Anderson, B. W.: Gem Testing, review by Dr. W. Campbell Smith, 339
- Anderson, Prof. E. W.: Appointed a medical visitor in the office of the Lord Chancellor, 577
- Anderson, Prof. J. R.: Appointment to Chair of Pathology University of Liverpool 579, 1132
- Andrade, Prof. E. N. de C., and Aboev, D. A.: Distribution of Grain Size in Annealed Metals, 68
- Andrews, Sir Christopher: Obituary of Prof. Wilson Smith, 1130
- Andrews, Prof. F. C.: Equilibrium Statistical Mechanics, review by Dr. P. J. Flory, 565
- Androgen Biosynthesis in the Human Adrenal Gland: Alternative Pathway of (Dr. G. L. Cohn), 297
- Angiotensin on Sympathetic Nerve Endings in Isolated Blood Vessels: Action of (A. Drazler, H. Lieben and Prof. H. P. Wolff), 764
- Angiotensinogen: Species Specificity in Reaction between Renin and (Prof. K. Anzawa et al.), 636
- Angle Distribution between the Electrons captured in the Outer Van Allen Radiation Belt: Equatorial (Prof. G. Calamai), 1179
- Ang et al. in the Presence of Mass Transfer: Measurement of Contact (A. B. Ponter and P. G. Thornley), 1288
- Anglo-Icelandic Field Research Group, 921
- Animal Behaviour and Drug Action (edited by Dr. H. Steinberg, A. V. S. de Reuck and J. Knight), review by Prof. R. D. Myers, 6
- Animal Cell Cultures: Nucleoside Incorporation in (Dr. John Seed), 296
- Animals and Plants: Far Southern (K. A. J. Wase and Prof. J. L. Green), 101
- Animals: Experiments on Living, 1338
- Anionic Polyelectrolytes on the Formation and Composition of Plasma Euglobulins: Effect of (Dr. A. J. Anderson), 408
- Ankle Joint: Reflex Innervation of the (Dr. M. A. R. Freeman and Dr. Barry Wyke), 196
- Annealing Investigations in High Dose Graphite (M. S. Stagg and J. A. Turnbull), 64
- Anoxia-Induced Release of Noradrenaline from the Isolated Perfused Heart (A. Wollenberger and L. Shahab), 88
- Anselone, P. M. (edited by): Nonlinear Integral Equations, review by Dr. M. A. Jaronov, 336
- Ant Trail Substance: Purification of the Fire (Christopher T. Walsh et al.), 320
- Antarctic: Atlas of the, 1035
- Antarctica: Power Spectrum of Sporadic-E at Wilkes and Byrd Stations (T. M. Noel and S. M. Bennett), 1182
- Anthocyanins in Plants (Dr. J. B. Harborne), 994
- Anti-arthritic Action of Brucylum (Prof. Phillip E. Laveque), 203

 Chemi-electron Emission from Alkali Azides : Chemi-luminescence and (G. D. Singer and Dr. H. J. Mueller), 1073  
 Chemi-luminescence and Chemi-electron emission from Alkali Azides (G. D. Singer and Dr. H. J. Mueller), 1073  
 Chemistry and Biochemistry of Antibiotics : Recent Advances in (Prof. H. Umetsu), *review* by Dr. A. M. Comrie, 1225  
 Chemistry and Physics : Handbook of (edited by R. C. Weast, S. M. Selby and C. D. Hodgman), *review*, 342  
 Chemistry : Isotopic and Cosmic (edited by H. Craig *et al.*), *review* by Dr. A. G. Maddock, 562  
 Chemistry : Methods in Polyphenol (edited by J. B. Pridham), *review* by Dr. P. A. Thompson, 1021  
 Chemistry : New Methods of Analytical (R. Belcher and C. L. Wilson), *review* by Dr. D. T. Lewis, 119  
 Chemistry, Oil and Gas in Romania : News and Commentaries, No. 1 1965, *review* by H. B. Milner, 693  
 Chemoreception : an Indicator of Systemic (Drug) Reactivity : Weber Ratio in Gustatory (Prof. R. Fischer *et al.*), 1049  
 Chemostimulation of Oviposition by the Cabbage Root Fly *Erosia brassicae* (Bouché) (R. M. M. Traynier), 218  
 Chemotaxonomie der Pflanzen, Band 3 (Prof. R. Hegnauer), *review* by Prof. L. Walicki, 119  
 Chemotherapy : Oncolysis with Laser Energy combined with (J. P. Minton *et al.*), 140  
 Cheng, Hwa-Sheng : Role of Exchangeable Potassium and Magnesium on Calcium Absorption on Marine Sediments, 1010  
 Cherin, Paul, *et al.* : A Computer Programme for Plotting a Crystallographic Fourier Synthesis, 391  
 Chervell-Simoo Lecture : substance of the sixth by Prof. R. V. Jones, 120  
 Cheshire-Shropshire Basin : Late Weichselian Glaciation in the (G. S. Boulton and P. Worsley), 704  
 Chersman, P. C. : Advances in Cancer Research, Volume 8, *review*, 340  
 Cheung, W. Y., and Williamson, Dr. J. R. : Kinetics of Cyclic Adenosine Monophosphate Changes in Rat Heart following Epinephrine Administration, 979  
 Chick, Dr. D. R. : Appointed Professor and Head of the Department of Electrical and Control Engineering, Battersea College of Advanced Technology, 577  
 Chick Embryo : Changes of Histone Composition in the Developing (Prof. L. P. S. Agnelli and E. G. Christensen), 638  
 Chick Embryo : Chromosome Marker Studies in the Graft-versus-Host Reaction in the (Dr. J. J. T. Owen *et al.*), 313  
 Chick Embryo : Localization of Tumours and Drugs on the Chorio-allantoic Membrane of the (K. Hellman and D. F. Tucker), 1408  
 Chick Interferon : Further Purification of (Dr. K. H. Pantel), 1298  
 Chicks : Serum Cholesterol Concentration in (Dr. A. Kronfeld *et al.*), 860  
 Chien, L.-C., *et al.* : Haemoglobin E in Vietnamese, 768  
 Chien, Prof. S., *et al.* : Comparison of Viscometric Behaviour of Suspensions of Polystyrene Latex and Human Blood Cells, 77  
 Child, Dr. R. : Coconuts, *review* by Prof. C. W. Wardlaw, 677  
 Childs, Dr. E. C. : Elements of Tropical Soil Science, *review*, 341  
 The Physical Chemistry and Mineralogy of Soils, *review*, 341  
 Practical Soil Science, *review*, 341  
 Chilton, Dr. O. P., *et al.* : Hybridization of Lactic Dehydrogenase *in vivo* and *in vitro*, 723  
 Chimaera : Serum Protein Formation of Donor Type in Rat-into-Mouse (Dr. Mildred E. Phillips and Dr. G. J. Thorbecke), 376  
 Chimeroids : Phylogeny of, 1240  
 Chinchilla : Culture *in vitro* of *Giardia Trophozoites* from the Rabbit and (Dr. E. A. Meyer and B. L. Pope), 1417  
 Chironomids : Parasitism by Larvae of *Usoaicola intermedia* Koenike, and another *Usoaicola* sp. (Acurina, Pionae), on (R. K. H. Jones), 317  
 Chironomids : Photoperiodic Control of the Maintenance and Termination of Larval Diapause in (Dr. W. Englemann and Prof. D. G. Shappirko), 548  
 Chloramphenicol Inhibition of the Growth of Green Algae (Dr. F. J. Taylor), 783  
 Chloride Solutions : Cadmium-Cadmium (Mario Fiorani and G. G. Bombi), 289  
 Chlorinity in Estuarine Mangrove Swamps, Florida : High Interglacial Water (David W. Scholl), 284  
 Chlorogenic Acid : Further Evidence for its Antigenic and Allergenic Activity (D. S. Bariana, J. Krupiec, L. M. Scurpaci, S. O. Freedman and A. H. Sabon), 1555  
 Chlorophyll *a* (L. Gaud (Morris trinitone L.) (Moraceae) : Presence of 1,3,6,7-Tetrahydroxyxanthone in Madurin from (A. Jefferson and Dr. F. Scheinmann), 1193  
 Chloroplasts of *Vicia faba* L. : Influence of loxymol on the Photo-reduction of Endogenous Plastoquinone by Isolated (D. Paxon and Dr. J. E. Smith), 1211  
 Chloroprene : Unusual Role of Dimers in Thermal Polymerization of (P. A. Leeming *et al.*), 403  
 Chlorpromazine and Fluphenazine : Comparison of T-Wave Changes in the Dog following Intravenous Administration of (Dr. G. L. Hassert, *jun.* *et al.*), 765  
 Cholecystokinin and Pancreozymin : Inhibition of Gastric Motility by a Commercial Duodenal Mucosal Extract containing (Dr. L. P. Johnson and Prof. D. F. Magee), 1401

## DISTRIBUTION OF SCIENTIFIC EFFORT

THE thirteenth annual report of the National Science Foundation\*, covering the year July 1, 1962–June 30, 1963, is the first annual report of the Foundation to be transmitted over the signature of the new director, Dr. L. J. Haworth. The activities described were carried out under Dr. A. T. Waterman's directorate and much of the interest of the report lies in Dr. Waterman's farewell statement as director. Essentially it follows the pattern of the twelfth annual report†, covering the year ended June 30, 1962, and earlier ones. Dr. Waterman's statement in the twelfth annual report is of particular interest, however, as it emphasizes the important new dimension acquired by science and one fraught with far-reaching social problems, namely, its potentiality for creating radical or large-scale changes in man's environment. Dr. Waterman's statement first directs attention to the major limitations imposed in the overall planning process by finance. In this connexion he observes that it is not sufficient merely to identify the immediate objectives, and proceed on the basis of studies of practicability, organization and procedure with a selected series of undertakings, basing the support of all scientific and technological activities on these specific objectives, in spite of the appeal of this approach from the point of view of management practice and efficiency. He emphasizes that our planning must encourage research in areas that are highly significant from the scientific point of view, and insists that we should not be limited by whether or not such research appears to have any immediate practical application. Basic research should contribute to the achievement of foreseeable objectives by providing assistance in all directions that science itself regards as significant and feasible.

Finance, however, is not the only limiting factor, and Dr. Waterman once again insists that the most important limitation is that imposed by manpower. He reminds us of the fact that there is a firm limit provided by the proportion of the population possessing ability to enter the professions of science and engineering—a factor to which insufficient attention is sometimes directed in planning the expansion of higher education in Britain. For a free society the problem, he suggests, is to identify and to stimulate the fraction of the population possessing such aptitudes and to provide for their education and training. Nor should it be overlooked that something like 40 per cent of students specializing in science and engineering should undertake academic careers if we are to be sure that sufficient research, and instruction of the high quality required, will be available to achieve our overall objectives.

This said, however, Dr. Waterman insists, as does the Commoner Report (*Nature*, 206, 1277; 1965), that it is

man's new capacity to effect major changes in his environment and in himself that should engage our most serious attention. Technical developments directly influence our environment on an unprecedented scale, and it may well be asked whether man is giving sufficient consideration to the possible consequences of experimenting on the present scale. Dr. Waterman points out that it is essential that we should fully recognize the dangers as well as the benefits that may attend modern research programmes and the application of new products on an ever-increasing scale. If every possible precaution is to be taken in experiments and pilot operations on a global scale, international co-operation is indispensable. He insists that it is essential that nations should come together in an effort to determine the extent of the hazards involved in such matters as nuclear explosions, water pollution and the manipulation of weather and climate, and to consider the types of controls that should be instituted. This is quite apart from the increasing extent to which the scale of the products involves resources far beyond those which a single nation could afford. Dr. Waterman concludes this statement by referring to some striking examples of successful international co-operation in this field, such as the International Geophysical Year and the programmes growing out of it, the International Year of the Quiet Sun and research on the upper mantle of the Earth's crust. The World Health Organization, the Food and Agriculture Organization, and the World Meteorological Organization of the United Nations provide other examples of successful international co-operation in science, while the United Nations Educational, Scientific and Cultural Organization has also played an important part, especially among the undeveloped nations. Necessity as the primary motive for discovery is fast disappearing, but we are now faced with innovation on a constantly growing scale, and with the question of whether we will continue to exploit Nature (including man himself) for immediate practical objectives with the minimum regard for possible long-range consequences. The greater the innovation and the larger the effort we devote to it, the heavier the responsibility for a thorough study of its purpose, motive and consequences. We should be seeking not merely knowledge but understanding and, to the extent that it is possible, wisdom. In this basic research the outstanding individual will always provide the most important and vital contribution.

Dr. Waterman's valedictory statement in the thirteenth annual report follows appropriately on his previous year's statement, being essentially a review and critical analysis of overall trends in research and development in scientific manpower, and their significance for national strength in science and technology. While the Federal Government played a leading part in providing funds and introducing and supporting large and critical programmes in the spectacular development of science and technology in the United States in recent years, Dr. Waterman points out

\* National Science Foundation. Thirteenth Annual Report for the Fiscal Year ended June 30, 1963. Pp. xxii+874. 1.25 dollars. (Washington, D.C.: Government Printing Office, 1964.)

† National Science Foundation. Twelfth Annual Report for the Fiscal Year ended June 30, 1962. Pp. xvii+868. 1.50 dollars. (Washington, D.C.: Government Printing Office, 1963.)

that the scale of the national effort demands careful consideration of certain questions. Among these questions the most important are: whether the grand total for research and development can be justified in the national interest in terms of money, manpower and other resources; whether the objectives of the undertaking represent a wise, prudent and adequate selection of national priorities; to what extent the component programmes in the effort are feasible and are intelligently designed to meet these objectives; whether the effort is conducted with proper efficiency and economy; and whether there exists, now and for the foreseeable future, the requisite scientific and engineering manpower. These are all points which call for consideration in framing scientific policy whether in the scientific field narrowly considered or on the wider national scale: they call for consideration by other Governments as much as by that of the United States, where the National Science Foundation was formed to facilitate the analysis of the facts and the review of the situation by competent and experienced persons.

Dr. Waterman returns fairly confident answers to the questions he asks. Since the National Science Foundation began to analyse the data in 1953, the sources of funds have changed very little, and while the Federal contribution increased from 53 per cent to 65 per cent, this increase occurred between 1953 and 1957 and has remained practically constant since. In basic research, however, the total funds are now nearly 1,500 million dollars, or about three times what they were in 1953, but as a percentage of the total they remained nearly constant at 8 per cent until two years ago, when they rose to 10 per cent, mainly through major new undertakings in such fields as oceanography, the atmospheric sciences, high-energy physics and space research. Somewhat less than 60 per cent of these basic research funds come from the Federal Government, while rather more than 25 per cent of the basic research is conducted in colleges and universities and about 16 per cent by Government. Statistically and fundamentally, the growth of science and technology among the three economic sectors over the past decades appears to have been balanced and consistent, and Dr. Waterman does not display the concern over space research which is manifested in the Commoner Report. Most of the research and development is being carried out directly in the national interest, and although the Federal Government is not acquiring a larger proportionate share in the investment in research and development, or encroaching increasingly on private and other sectors, these conditions may not always apply within particular programmes, projects or areas of science. If, therefore, any substantial economies are to be effected, they must be applied to the 90 per cent of the effort directed towards practical objectives and not in the basic research effort, unless the economy is to be disastrously affected.

Basic research, Dr. Waterman insists, provides the foundation for technological advance, as well as determining the potentialities of scientific progress and providing the essential advanced training for scientists and engineers. As to the capacity of the United States to support its present effort, he again believes that the limiting factor is the number of scientists and engineers available and the extent to which facilities for their education and training are available. Here it is the time scale that is immediately critical. Generally, he points out, the studies of the National Science Foundation suggest that the employment of scientists, engineers and technicians will be doubled by 1970, and the education and training of

this particular group can be achieved without depriving the country of the professional skill required in other fields. Although the scientific manpower problem is very urgent the underlying problem is the much broader one of providing thoroughly competent training in all fields, and Dr. Waterman suggests that the opportunities for radical improvement in general education in the United States are very great. He refers to evidence that careful attention to the improvement of elementary courses in standard subjects could be decisive in producing effective long-range results. His observations fully substantiate the argument for giving much greater attention in Britain, also, to the revision of courses in science subjects at all levels.

Dr. Waterman has some cautionary words about the support of basic research by the project system which should be noted carefully by those who are inclined to extend the contract system in Britain. He also notes the problem of continuity involved in the establishment of special research centres with only limited interests, whether by the Government or otherwise. In a similar context, he suggests that the sponsorship of special integrated programmes in such areas as oceanography, atmospheric sciences and high-energy physics should not be allowed unduly to curtail support for individuals in other fields of science. In his 'farewell review', however, the emphasis is placed on the critical importance of fundamental research and on ensuring that this is allowed to develop freely, uncontrolled by political or social considerations. For this he recognizes that there must be a fuller public understanding of science as well as of technology and that to clarify the understanding of the distinction between science and technology provides an important starting point. Like the Commoner Committee, he recognizes that some of the decisions cannot be taken by scientists or technologists themselves, because they involve social and political issues; but there must be some general public understanding if the decisions taken are to be intelligent or appropriate. As in his previous statement, he concludes with a reference to the importance of international co-operation in this field. The statements illustrate how much the National Science Foundation has owed during the years to Dr. Waterman's leadership and how well deserved are the tributes which his successor pays to him in his own statement in the fourteenth annual report of the Foundation\*, covering the year ended June 30, 1964.

Dr. Haworth devotes that statement to outlining his views concerning the role of science and technology in national affairs, the responsibilities of the Federal Government for promoting science, technology and education in the public interest and, particularly, the part played by the National Science Foundation. It is interesting to note the extent to which he places his chief emphasis on exactly the same points as does Dr. Waterman, and especially on those which have recently been stressed in the Commoner Report on the integrity of science. He insists, for example, that in spite of their interaction and overlap, research and development are separable and separate entities, and that expenditure on development should be justified on grounds relating to its final purpose and should not be competitive with expenditure on basic research, or even on broadly based applied research. Again, while all development, and much

\* National Science Foundation. Fourteenth Annual Report for the Fiscal Year ended June 30, 1964. Pp. xxix+128. 45 cents. (Washington, D.C.: Government Printing Office, 1965.)

applied research, is directed towards specific national goals, it is more important to ask, not how much we can afford for research and development but how necessary a particular undertaking is to the achievement of a national goal. Criticism and appraisal must be specific, and Dr. Haworth is as clear as Dr. Waterman as to the vital importance of public understanding: the real objective in basic research is to develop an understanding of Nature.

There is no misconception of the importance of all those areas of activity—basic research, applied research, and development—or their interrelationship. Dr. Haworth suggests that scientists might have done more to explain clearly the nature of basic research. One of the most important features of his statement is his survey of the role of the National Science Foundation, including some specific criticism of the project grant system as hitherto used. This is the more valuable in that it is placed in the context of the historical perspective rather than simply expressing a conviction that scientific and technological progress depends alike on strengthening education in science and on maintaining and augmenting a fund of scientific knowledge, derived mainly from basic research. In this historical perspective he notes particularly the limitations which manpower, facilities and finance always impose on policy, the necessity of guarding against fragmented research effort or dissipation of resources, the extent to which scientific activities transcend the responsibility or interest of a single agency, and the need for continuous reappraisal from fresh vantage points.

In the United States Dr. Haworth considers that the key individual in co-ordinating the national research and development effort is the Special Assistant to the President for Science and Technology, who is chairman of the President's Science Advisory Committee and of the Federal Council for Science and Technology as well as head of the Office of Science and Technology. The Federal Council for Science and Technology consists of the chief scientific officers of the nine Federal agencies most heavily involved in scientific activities and it leans heavily on the scientific advice of the Science Advisory Committee and National Academy of Sciences. It is under this system that the National Science Foundation operates and it has in the past relied heavily on project grants in supporting research. Dr. Haworth now asks whether the Foundation should attempt instead to devise new or modified programmes of support; how the Foundation can be sure that the relative amounts of support provided to the various fields of science are approximately correct; and whether the Foundation should change its policies and procedures in response to increasing concern over the geographical concentration of Federal funds for research and development.

Even in the United States these problems are not limited to the National Science Foundation, and in Britain they are implicit in the concern at present being expressed over recent changes in the organization of civil science. Dr. Haworth points to some specific defects in the project grant system. • It leads, for example, to decisions being made outside the institution on the nature and amount of support to be given to the parts within a particular institution, and this may adversely affect its balanced growth or administration. Again, scientists and administrators may alter the proposed balance of research in favour of efforts judged most likely to receive Federal support. Younger, unknown investigators tend to have difficulty in securing support, and it is also difficult for

an institution to establish new activities, particularly interdisciplinary units or programmes. Under this system, too, funds are not often available for flexible or co-operative use, and experienced research workers are sometimes required to submit fresh applications for continued support every year or two, when the nature of the work makes it evident that completion of the project requires much longer.

Dr. Haworth does not suggest that there is any simple way to overcome these difficulties, although they might become less pressing or acute if more generous funds were available. What is clear from his statement is that under his leadership the Foundation will continue to seek for new and improved methods of allocating its funds effectively, including the assessment of priorities as between different fields of science and their probable contribution to the solution of national problems. He is obviously animated by essentially the same convictions as his predecessor and, so far, he appears to have limited himself to some measures to encourage decentralization within the Foundation itself. However, on the evidence of his first statement the Foundation should continue to function on the sound lines established in the past, but with constant appraisal of its methods and procedures in the light of past experience, new needs and resources and changing national requirements. To scientists in Britain, the Foundation's report and the director's statement should provide a wealth of material for appraisal of the reorganization of scientific effort and the structure most appropriate for that effort and for the formulation of scientific policy.

## ORGANIZATION AND EVOLUTION IN PLANTS

### Organization and Evolution in Plants

By Prof. C. W. Wardlaw. Pp. xiii + 499 + 24 plates. (London: Longmans, Green and Co., Ltd., 1965.) 80s. net.

IN Prof. Wardlaw's latest book, a worthy successor to earlier and familiar volumes<sup>1-3</sup>, the author faces the problems which biological organization presents. He therefore deals with what many regard as one of the most outstanding scientific problems of our time. The book relates specifically to plants, and here one should frankly recognize that it is in their organization that higher plants and animals differ in essential respects. The breadth and scholarship with which Wardlaw develops his theme will be appreciated by all plant scientists, who accept the great challenge of interpreting growth, development, differentiation, and morphogenesis, for they are, and will increasingly be, preoccupied with organization in living things. Nevertheless, there are those to whom the topic of organization carries a suggestion of vitalism and even mysticism. But even they must see that, whereas comparative biochemistry and now molecular biology tell us much about what cells and organisms have in common, we still face the problems of their diversity. It obviously takes something more than a general knowledge of the separate parts of a complex system to understand its smoothly co-ordinated, integrated behaviour.

Prof. Wardlaw's book, which deals with problems of organization at various levels of complexity, is therefore a timely one, for biologists must now turn increasingly to the consideration of the implications of organization as they investigate biological functions, not only in isolation, but also in the full complexity of their interactions in living systems which can grow and develop. While it is a laudable chemical ambition—and even a necessary first

step—to achieve as much as possible in cell-free systems, knowledge is rarely complete until we interpret the behaviour *in vivo*. In this respect the present-day popular term 'molecular biology', if too literally interpreted, can become a *reductio ad absurdum*; for the problems of biology really begin when one considers levels of organization higher than the purely chemical interpretation of molecules—molecules *per se* are not alive. Indeed, without the examination and interpretation of viable systems, which have evolved and which can grow and develop, biology would be like 'Hamlet without the Prince of Denmark'. Prof. Wardlaw therefore summarizes the knowledge that has been gleaned from the various branches of natural science, and which is now needed to formulate concepts of the organization of plants. However, he also draws extensively on a wide knowledge of works which deal with the comparative morphology of plants and with the philosophy of organisms. Ever appreciative of the essential contributions which have been made and are still to be made by students of chemistry and physics, etc., he nevertheless stresses—and rightly so—the need to see and understand the organism as a whole.

This book is therefore to be welcomed. It will be welcomed by those botanists who are steeped in a descriptive tradition, because of the skill with which Prof. Wardlaw summarizes knowledge drawn from a scattered and extensive literature. It should be welcomed by experimentalists, who may turn to it for an appreciation of the systems with which they often do their work. It should be helpful to those in biochemistry, biophysics and molecular biology if they really seek to understand the full range of problems which the interpretation of plants as organisms presents. But all biologists will readily appreciate the twenty-four carefully chosen and well-executed plates in this attractive volume, and the large number of figures which illuminate the text and develop the author's theme around concrete and well-chosen examples. Thus, this book should be useful to students, teachers and research workers alike for the wealth of documented material it contains. The bibliography comprises into some 750 citations the selected references by which the author skilfully exposes his readers to a very extensive body of literature. The subject index also functions as an index by plant names.

Prof. Wardlaw views the biological scene with the perspective of a morphologist and he emphasizes a comparative approach; his essential and indisputable claim is that biological organizations have evolved and, to survive, they have adapted and must function effectively. But, with the scope and breadth of interest which distinguishes Prof. Wardlaw's writings, this new work ranges from current knowledge of genetically determined events as they occur in nature at the molecular level to the recognition of organization at successively higher levels. Thus organization is considered at the level of sub-cellular organelles, cells, tissues, organs, and organisms; and only at the level of populations, where problems of organization also arise, does Prof. Wardlaw content himself by reference to other authorities. But, throughout, the author is essentially true to that which he knows best, namely, the comparative morphological approach. Collectively, organisms are seen as the product of their history of evolutionary adaptation, and, individually, as the outcome of their ontogenetic development. Thus time is an essential parameter.

Prof. Wardlaw's book is particularly needed, as investigators now make use of more and more refined techniques but also tend to draw broader generalizations from a narrower base of observations. Not all investigators find themselves able to build on the philosophical writings of the past nor to formulate that broad appreciation of plants as successful functioning organisms which is the necessary base from which to approach the still unolved biological problems. Prof. Wardlaw's book seems very successfully to have contributed to this end; it

sketches in the biological background against which the emerging drama of the growth, differentiation and morphogenesis of plants may now be viewed.

It is neither possible nor profitable to make a digest, or a précis, of the sixteen separate chapters which comprise *Organisation and Evolution in Plants*. Were that possible, neither the book nor the subject to which it refers would have the fascination of a continuing, unfolding, unfinished story. The author would clearly have it so. He concludes, however, on a somewhat wistful note, designed to preserve the unity of the subject of botany.

Some (as Prof. Wardlaw says) seem now to regard botany as a "Cinderella-like science", only likely to attract general interest in so far as its problems are "tackled by those with competence in the physical sciences". It is even feared that botanical science will almost certainly suffer a setback "even cease to be botany" if "purely physico-chemical concepts of some of the processes in plants were permitted to displace and supervene upon the comprehensive biological concepts which are essential to any adequate understanding of plants as functional entities". Surely, however, Prof. Wardlaw need have no fears. Plants are not animals; neither are they mere assemblages of molecules any more than a chemical analysis alone describes the Five Sisters' window of York Minster or the beauty of the stained glass in Chartres Cathedral. So long as there are those who set down with skill and scholarship the facts as Prof. Wardlaw has presented them, and others take up the problems as he, and they, see them, there will be need for those who can take all the knowledge that chemistry and physics and molecular biology can furnish to develop concepts of what plants are and how they function through growth. One may even say that the students of plants as organisms are needed not only to pose the problems that the new disciplines may solve but to suggest the systems on which the attack may best be made. The ancient injunction to "consider the lilies of the fields how they grow" is still apt, to be heeded with wonder and humility by botanists and chemists alike.

To put the matter more bluntly, the dominant organisms of to-day are plants, for they collectively represent the bulk of living protoplasm now on the Earth, and without them there would be no animals or insects. This is not alone because of photosynthesis but also because it is plants that have solved the problem of incorporating inorganic forms of nitrogen into protein and which keep the nitrogen cycle going. One could have an extensive biology without animals, but not as we know it without plants. Higher plants also have distinctive ways by which they construct their organs out of cells and by which they correlate and regulate their behaviour; they have obviously achieved a very different way of life than have higher animals. Therefore, that branch of biological science, hitherto called botany, will and must persist. Botany is no "Cinderella science"—the stately theme which Prof. Wardlaw himself develops will not fade like a fairy-tale at midnight. It contains too much that is essential to human welfare and too much that still remains to challenge the combined abilities of biologists and of those who, following Wardlaw's advice, will add to the skills of the chemists and physicists that intimate knowledge of, and respect for, organization at all levels which is the distinguishing characteristic of the biologist.

The cell theory of 1838 defined the minimum viable morphological unit. Huxley's famous aphorism that "protoplasm is the physical basis of life" focused attention on a "stuff of life". Since then past progress has so often been made by, as it were, taking living organisms apart to achieve an ever more detailed knowledge of them at lower and lower orders of magnitude. But with each new technique that basis of life which used to be thought of as a substance becomes ever more obviously an arrangement, a design, composed of organelles and granular units in complex and intimate proximity. All this knowledge of fine structure is in a descriptive morphological tradition.

Meanwhile the molecular biologists, approaching the the problems from the other end of the scale, strive to interpret the living system in terms of the unit properties of its matter. But after all this essential learning of 'more and more about less and less', biologists must still attack the difficult task of synthesis. They must, in effect, put the pieces back together again; not merely to visualize the reconstructed wholes built out of their identifiable parts (granules, membranes, organelles, cells, tissues, organs) but also to interpret how organisms function—in short, how they grow and develop. (Having in fact understood the watch by taking it to pieces, we must not only visualize how it should be reconstructed but understand what makes it tick.) It is here that the seemingly more intangible concepts of organization apply, for they relate to features which—though they may distinguish the "quick from the dead"—are more evident in the subtleties of the assembly and interrelationships between component parts than in their identity alone. It is all this which makes for a smoothly operating integrated whole.

Prof. Wardlaw would have us understand plants, whether algae or angiosperms, in this way; and his book *Organization and Evolution in Plants* makes a real contribution to this end, if only because it directs attention to the problems that are to be encountered.

## INTEGRATED BIOLOGY

The Behaviour of Arthropods

By J. D. Carthy. Pp. vii+148. Paperback 12s. 6d.

The Biology of Hemichordata and Protochordata

By E. J. W. Barrington. Pp. vi+176. Paperback 15s.

The Physiology of Nematodes

By D. L. Lee. Pp. x+164. Paperback 12s. 6d.

The Metabolism of Insects

By Darcy Gilmour. Pp. xii+195. Paperback 15s.

Reproduction in the Insects

By K. G. Davey. Pp. x+96. Paperback 12s. 6d.

Cybernetics and Biology

By F. H. George. Pp. viii+138. Paperback 12s. 6d.  
(Edinburgh and London: Oliver and Boyd, 1965.)

THE past twenty-five years have seen the disappearance of the once well-defined boundaries separating classical biology from biochemistry, physics and chemistry. Recognising this fact, some universities have now begun to establish integrated courses in biological science in which biochemistry and the exact sciences carry equal weight with botany and zoology and in which the latter subjects are themselves biased toward experiment and analysis. But the biologist is still primarily concerned with the organism as an integrated whole; the ultimate explanations of physiology and morphology in terms of physics and chemistry must still account for the diversity of living things and the ways in which organisms exist in relation to their particular environments.

The six volumes included so far, in the series of *University Reviews on Biology*, separately and together form an admirable addition to the literature at present available to support this new approach to biology. The books combine classical zoological information with the results of modern experiment, and stress particularly the importance of biochemical processes in arriving at a deeper

understanding of biological function. The reviews should play an important part in any integrated course in biological science, although since the individual subjects are largely unrelated, the books may be bought separately according to particular interest.

*The Behaviour of Arthropods* is another example of Dr. Carthy's happy knack of communicating fairly complicated concepts in terms readily understandable to the non-specialist. The book eschews purely descriptive accounts of behaviour patterns and consequently deals largely with insects, the group in which most detailed analysis has been made; where equally rigorous research has been carried out in other arthropod groups, this has been included. The various characteristics of different kinds of behaviour are related, where possible, to the neurophysiological mechanisms involved. The excellent summaries of Mittelstaedt's analysis of the control pattern of prey localization in mantids, and Harker's work on cockroach diurnal rhythms, are typical of the quality of this book.

*The Biology of Hemichordata and Protochordata* discusses the morphology and interrelationships of the groups in a way which might be thought to follow the more classical accounts of animal phyla. But the anatomical descriptions provide a firm basis for a great deal of recent work on movement, feeding, reproduction, etc. And, as is to be expected in a book by Professor Barrington, there is an amount of stimulating speculation on the origins of the thyroid and pituitary glands and hormones. A special feature of this volume is the concise summary following each chapter.

*The Physiology of Nematodes* also includes sufficient anatomical detail, including ultrastructure, to make more meaningful the biochemical events underlying the physiology of the various kinds of free-living and parasitic nematodes. The metabolic processes of digestion and absorption, oxygen uptake and transport, osmoregulation and excretion, etc., in nematodes are continually compared with similar processes in other animals, to illustrate clearly the universality of these mechanisms and their specific variations related to the mode of life of particular forms.

*The Metabolism of Insects* is a biochemical text related particularly to insect biology. Where information about metabolic processes in insects is incomplete, Dr. Gilmour has indicated the probable course of events by drawing upon general biochemical knowledge. But the sections concerned with mechanisms more specific to insects, for example the metabolism of insecticides, tanning of the cuticle, or the intervention of hormones in the control of metabolism, are dealt with in remarkably lucid detail. Each chapter is introduced in general terms, describing principles in a way easily appreciated by the non-specialist, before moving to the more detailed biochemistry involved. This book will be invaluable both to the general entomologist and to the biochemist.

*Reproduction in the Insects* does not attempt a comprehensive review of insect reproductive mechanisms, but concentrates more upon some of the specific problems involved. Dr. Davey shows how modern research has brought a greater insight into the kinds of reproductive mechanisms evolved by the largest animal phylum as well as a clearer understanding of the ways in which different insects have developed a variety of processes to deal with similar problems. The chapters on spermatophore formation, sperm transfer and hormones are particularly good. The author's enthusiasm and clear exposition illuminate the whole of this little book.

*Cybernetics and Biology* is perhaps the least successful of this generally very successful series. Every field of intellectual activity tends to develop its own esoteric jargon; this becomes particularly confusing in psychology and cybernetics, where words and phrases lose their everyday usage and have specific and perhaps unusual meanings. Dr. George suggests that the Penguin Dictionary of Psychology be consulted for the definition of some of the terms

he uses—a revealing admission in a book about the science of control and communication! But, once this barrier is overcome, the book repays careful study; it can add considerably to an understanding of some of the problems discussed, for instance, by Dr. Carthy in his book. In fact, Dr. George stimulates thought about the various principles which may be involved in a great many biological processes that are usually taken for granted.

The authors of these volumes have evidently had few limitations imposed upon them by the publishers—as should be the situation when they are as expert in their subjects as these. The books are of various lengths, and exhibit a variety of treatment; but each one contains a longer or shorter list of references for broader or more detailed reading. In paperback or hard covers, the series is very well produced, with illustrations that are generally good although differing a little in quality from volume to volume. If subsequent volumes in the series maintain the standards set by the first six, then *University Reviews in Biology* will become a valuable, almost indispensable, part of the libraries of university students and teachers alike.

## CONTROL OF GLYCOGEN METABOLISM

### Control of Glycogen Metabolism

Edited by Dr. W. J. Whelan and Margaret P. Cameron. (A Ciba Foundation Symposium.) Pp. xiv + 434. (London: J. and A. Churchill, Ltd., 1964.) 60s.

THE latest addition to the invaluable series of Ciba Foundation symposia generously covers the field described in its title. The range of the numerous papers presented permits discussion of the synthesis and catabolism of glycogen, and its control by enzymatic and hormonal influences, together with an important section on the glycogen storage diseases. The editors, and in particular Prof. W. J. Whelan, are to be congratulated on the skilful way in which the complex assembly of papers and discussions on papers has been welded into the unified text of a book of great importance.

The book begins with a most stimulating article by French on the structure of glycogen evolving a concept of steric limitation in size of the Meyer model. This, together with the paper by Orrell, Bueding and Reissig, which offers a careful evaluation of the methods of preparing undegraded glycogen, serves to visualize the molecule and to restate the problems still unsolved in the structure of the particle.

A large section of the symposium is given up to papers on the present-day viewpoints of such enzymes as phosphorylases, branching and debranching enzymes. Here particularly the papers by E. G. Krebs *et al.* on the nature of the phenomenon leading to the appearance of catalytic activity in the phosphorylase molecule and its control are of great interest. This work receives interesting cross-illumination from the papers of Cori and Brown, who individually discuss the contribution of phosphorylase to the determination of the structure of glycogen and its role in the regulation of glycolysis in skeletal muscle. The further paper by Sutherland on the location of adenylyl cyclase and adenosine 3',5'-phosphate deserves close attention, as do the discussions which follow each of these accounts. Here perhaps is the most stimulating part of this book and clearly by the co-operative picture that emerges on present-day concepts of phosphorylase action more than justifies the assembling of so many talents together in a symposium.

Though so much work on one enzyme might suggest the neglect of others, the great variety of articles by the groups of Whelan, Lerner, Brown and Hers would firmly refute such an imputation. Part of the problem would appear to be that there are more enzymes known than

there are physiological functions for them to fulfil. However, much information is now available on the mechanism of debranching of glycogen structure. One wish that I would make is that some suitable enzyme nomenclature for these catabolic reactions should emerge in the near future. In addition, the papers by Lerner on the branching enzyme and Hers on the mechanism of action of amylo-glucosidase demonstrate the subtlety of experimental approach needed in elucidating the action pathways. Rosenfeld's paper reports a new mammalian enzyme— $\gamma$ -amylase—and reports on  $\gamma$ -dextrins. The paper by Prof. Whelan *et al.* lies at the heart of what may be called the Cori-Whelan controversy as to the structure of the branched chains in glycogen; there can be little doubt that Prof. Whelan is correct in his deductions.

The paper by Leloir on the role of uridine diphosphate glucose in the synthesis of glycogen is a model of lucid presentation and relevance, as anyone who heard his opening lecture in New York in 1964 will agree. One aspect which he mentioned there and which provoked much thought was his interpretation of the phosphorylase activation mechanism. Following Macfarlane's explanation of blood clotting as a multiplying system serving as a biochemical amplifier (*Nature*, 202, 498; 1964), Leloir postulated that a similar cascade of proenzyme-enzyme transformations might serve just such a purpose in the interconversions centred around the phosphorylase molecule.

Later articles in the symposium deal with the difficult territory of hormonal interaction on physiological systems, and the interpretation of these and other effects in terms of control over the enzyme sequences involved. Noteworthy in this class, of course, are the papers by Morgan and by Lerner. The former is a closely argued account of the allosteric properties of phosphorylase *b* studied in the perfused rat heart where glycogenolysis had been stimulated by glucagon and anoxia. Lerner's paper deals with the role of insulin in the control of glycogen synthetase. Together with these papers, the account of Bueding on the effects of adrenaline on intestinal smooth muscle, and the speculations of Randle on some indirect actions of adrenaline on glycogen metabolism, give this section of the symposium a pleasing sense of integrity.

The final section of the symposium deals with glycogen storage diseases. This is well presented; many of the previous contributors who dealt with the biochemical implications return to deal with the clinical quandaries of the subject. In particular Manners, whose excellent review of glycogen metabolism appeared in 1963, discusses type I glycogenosis, and is followed by other workers discussing the known diseases. Stimulating possibilities exist in the finding by Spencer-Peet of cases of glycogen synthetase deficiency.

The symposium closes with a discussion and a recapitulation of the main thoroughfares of glycogen metabolism.

C. F. PHILLIPS

## RECENT ADVANCES IN PSYCHOPHARMACOLOGY

### Animal Behaviour and Drug Action

Edited by Dr. Hannah Steinberg, A. V. S. de Reuck and Julie Knight. (Ciba Foundation Symposium jointly with the Co-ordinating Committee for Symposia on Drug Action.) Pp. xiv + 491. (London: J. and A. Churchill, Ltd., 1964.) 67s. 6d. net.

THE major part of *Animal Behaviour and Drug Action* is a compilation of papers and discussions presented at an international symposium, the aim of which was to examine the role of animal behaviour in investigations of drugs affecting the central nervous system. The book constitutes a welcome addition especially to the bookshelf

of the experimental psychologist, whose knowledge of psychoactive drugs could well be broadened, because the participants representing physiology, pharmacology, psychology and biochemistry laid emphasis, as could be expected, on the drug action rather than on the animal behaviour side of psychopharmacology.

A number of important issues were raised at the symposium. One which surely must merit future consideration is the role of the blood/brain barrier and blood/cerebro-spinal fluid barrier in psychopharmacological investigations. For example, RNA administered systemically may affect the rate of learning in an animal (Cook), yet there is no evidence that RNA penetrates the blood/brain barrier. It is also well known that if given intracerebrally rather than systemically, the biogenic amines can exert very different actions (Feldberg). In this connexion, one of the highlights of the symposium was the elegant work on the development of the blood/brain barrier in chicks, which showed how pharmacological, neurophysiological and behavioural techniques could be simultaneously applied to one problem (Dewhurst and Marley).

Another issue introduced was the importance of studying effects of drugs on social behaviour in animals (Chance and Silverman). Although this sort of approach appears promising, interpretation of the action of psychotropic drugs on social interactions among animals is difficult. It is questionable whether a drug which suppresses aggressive behaviour of rats possesses a corresponding effect on analogous behaviour in humans. However, in spite of methodological limitations, it is encouraging to learn that astute attempts are being made to translate the subtle psychogenic action of a drug from rodent to man.

The difficulties which may arise in the usage of behaviour analyses for drug evaluation were stressed (Irwin). For example, drugs can exert different effects if the animals tested differ in their "emotional and intellectual" states (Rushton and Steinberg), genetic backgrounds (Broadhurst), nutritional states (Watson), or even their familiarity with fellow test-subjects (Wilson and Mapes). With the use of the operant bar press as a research tool, a single drug may enhance a particular response topography with one schedule of reinforcement and depress it with another (Dews). Since reinforcement schedules can be varied *ad infinitum*, some interpretation is obviously desired in the meaning of the response change associated with changes in such schedules. One always wonders whether psychopharmacological studies utilizing an operant paradigm in animals with little or no cerebral cortex (birds) really bring us any closer to the understanding of psychoactive drugs, especially if these compounds are ultimately intended for clinical extension to humans.

Papers on the long-term effects of chronic administration of drugs were noticeably absent. Some coverage could have been given to those drugs which create profound social disturbances and on which experimental findings have emerged recently, namely ethyl alcohol, morphine, and other so-called 'addictive' compounds.

The discussion sessions which make up the final portion of the book were intended to be an organized exchange of ideas between the frequently divergent disciplines within the area of psychopharmacology. As a general impression it seemed that, in coming together, each discipline could be likened to an orchestral ensemble but each playing a different melody at the same time in the same concert hall. Because each contributor learned almost entirely on the literature within his own discipline, discussion often was disjointed, lacking in continuity, and sometimes switched abruptly from one topic to another with important points hanging in the air.

In spite of this criticism, the organizers of the meetings must be congratulated on the final endeavour. By virtue of discussion sessions of the quality recorded in this

volume, and as disciplines become better acquainted with one another's experimental techniques and points of view, future interdisciplinary meetings will become increasingly more fruitful.

R. D. MYERS

## PALAEOCLIMATE AND PALAEOMAGNETISM

### Problems In Palaeoclimatology

Edited by A. E. M. Nairn. (Proceedings of the NATO Palaeoclimates Conference held at the University of Newcastle upon Tyne, January 7-12, 1963.) Pp. xiii + 705. (London and New York: Interscience Publishers, a Division of John Wiley and Sons, Ltd., 1964.) 147s.

THE introductory article to *Problems in Palaeoclimatology*, by Prof. W. H. Bucher, is aptly entitled "The Third Confrontation". It draws analogies between the present impact on geological science of ideas on palaeogeography and palaeoclimates stemming from studies of rock magnetism, and the better-known geological-geophysical conflicts of the past concerning the age of the Earth and the origin of ocean basins. The reader of the book will doubtless find a fourth confrontation, between the apparent precision and repeatability of the palaeomagnetic observations (although their interpretation is still far from certain) and the failure of geologists to agree on the very nature of the phenomena which they seek to elucidate.

Thus in a series of successive geological articles on Precambrian glaciations, we find the conflicting conclusions: (1) "At present no Precambrian tillite has been sufficiently studied for us to accept glaciation without reservation"; (2) "The whole globe was glaciated in Eocambrian times"; and (3) "The evidence for late Precambrian glaciation is remarkably widespread". Without attempting to resolve these opposing opinions, it should perhaps be observed that recent dating work has shown many of the supposed late Precambrian 'tillites' to be more widely separated in age than is the Lower Cambrian from the Pleistocene; and that the presence of extensive phosphorites in the Sinian of China and Riphaean of Russia is scarcely compatible with the hypothesis of a lengthy and world-wide Precambrian glaciation, the end of which triggered off the rapid evolution of a Cambrian fauna.

A similar conflict is seen in the separate contributions of two authors on the late Precambrian conglomerate near Caen in Normandy, one of whom concludes that this formation is "as indicative as the Eocambrian fluvioglacial deposits of Norway or even the Quaternary fluvioglacial deposits of Poland", whereas the other asserts that "None of the data permits us to make inferences about climate. The climate could have been anything from tropical to glacial".

The work is, however, concerned with a great deal more than problems of Precambrian glaciation. It comprises no less than 54 contributions, arranged in chapters on the use of fossil plants in palaeoclimatic interpretation, the evidence of climate from coal and coal measures, the recognition of ancient glaciations, Precambrian glaciations, geophysical techniques and ancient climates, Devonian climate, theoretical considerations and Quaternary climate, the recognition of arid climate and wind direction studies, Permian climate, palaeontology and climate, and problems of red beds and soils. Dr. A. E. M. Nairn's editorial work is of outstanding quality, the diverse papers being bound together into these chapters by a unifying theme and by means of a well-summarized discussion at the end of each. Many of the contributions are entertainingly controversial and the book certainly deserves a place in every geological library for the use of mature readers, but it is to be regretted that the price is much higher than one expects to see for the report of a meeting which was financed from public funds.

C. F. DAVIDSON

### Massive Radiation Techniques

By Sidney Jefferson. Pp viii+324. (London: George Newnes Ltd., 1964.) 70s.

THE development of nuclear reactors during the past two decades has made possible the large-scale production of very strong radioactive sources. One result of this has been that some of the useful effects of ionizing radiation found in research laboratories can now be applied on the grand scale to a variety of technological problems. *Massive Radiation Techniques* surveys such applications in a number of industries with particular reference to their commercial viability. In some of them, for example the preservation of food and the sterilization of medical equipment, irradiation has to compete with well-established methods. In others, such as insect pest control by sterile male release, sterilization by gamma-irradiation may be the only feasible method. This is illustrated by the carefully planned operation of rearing, sterilizing and releasing 2.5 billion screw-worm flies in the south-eastern states of the United States which resulted in the virtual eradication of this livestock pest from the selected area in 1959.

The non-specialist will find that the lucid introductory section on the interaction of ionizing radiations with matter will make few demands on his previous knowledge while the final chapter on dosimetry will provide him with a short but adequate account of methods at present in use and the dose ranges over which they are best used.

The most widely used sources in large-scale irradiations are  $^{60}\text{Co}$  and electron accelerators and the engineering problems associated with their use, including automatic feed systems for packaging materials, are illustrated by examples of installations which have been operating for some years. Other topics covered at length include the biological effects of massive radiation doses in relation to agricultural problems and plant breeding and the use of radiation in the chemical industry.

The text is very free from errors and the numerous figures are with few exceptions clear and well prepared. The extensive bibliography which accompanies each chapter will be welcomed by the serious student.

This is a book which should stimulate ideas among industrialists and also provide a basis for planning the exploitation of useful radiation effects. R. J. MUNSON

### Automatic Methods in Volumetric Analysis

By D. C. M. Squirrell. Pp. x+201. (London: Hilger and Watts, Ltd., 1964.) 42s. net.

NINE-TENTHS of *Automatic Methods in Volumetric Analysis* is devoted to the description of automatic methods of end-point detection in volumetric analysis and as such is a bench working manual of considerable value. It is complementary in content to the work by J. F. Phillips, entitled *Automatic Titrators*.

The subject-matter is subdivided into four major parts: titrations to present end-points; full-scale recording potentiometric methods; full-scale titrations in non-aqueous media; and some other instrumental titration methods. Each part is headed by a section entitled "Principles and Instrumentation", which is followed by detailed description of a number of methods to illustrate the points elaborated. Many of these have been drawn directly from the author's own experience and are products of his fruitful association with Dr. Haslam. The methods described have been chosen to cover a wide field of general analytical interest and include determinations of total nitrogen in organic matter, water by Karl Fischer reagent, halides, sulphates and metals by ethylenediamine tetraacetic acid.

Much of the apparatus described has been assembled from a variety of component parts, some home-made, and many others are commercially available units. In some examples sufficiently detailed diagrams and circuitry are given to enable the reader to design and build similar equipment for a particular method.

Further stages in the development of completely automatic analytical systems are only briefly described, but an understanding of the basic principles elaborated in this book is a necessary prerequisite to such developments.

Minor editorial faults, which serve as irritants, exist in the text, for example, the calculation of titrant volumes from recorder chart inches, titration times or syringe plunger movement are stated and re-stated in full. A uniform presentation of reagents, used in the various methods is also required.

The book is, however, an invaluable collection of techniques and instrumental methods and as such is worth its place on any analytical laboratory bookshelf.

R. SAWYER

### Genetics In the Atomic Age

Second edition. By Charlotte Auerbach. Pp. vii+111. (Edinburgh and London: Oliver and Boyd, 1965.) 7s. 6d.

THIS is the sort of book which ought to be freely available in common-rooms, school libraries and reading rooms, wherever people, especially young people, with enquiring minds might be likely to pick it up and thumb through it. It is small, short and inexpensive: the sketches by Miss I. G. Auerbach invite perusal: the text is entirely readable, without technical terms or quantitative expressions: and a curious glance stands a good chance of being followed by a thorough reading. The result would be many more people with an interest in the genetic future of man, and the knowledge needed to form a rational view of the dangers of exposing his germ-plasm to ionizing radiations.

Since the first edition in 1956, Dr. Auerbach has revised and brought the book up to date. The first few chapters deal with what mutations are, how they affect the organism and the species, and how they are inherited. Then comes a discussion of the ways in which ionizing radiations act on genes and chromosomes. In the last chapter the application of this knowledge to man in relation to his genetic future is set forth with the clarity, reasonableness and force for which the author is already well known.

For those whose point of view is already formed and who are trying to reduce mankind's present genetic exposure to radiation, the book offers authoritative support and invaluable ammunition for argument.

ALMA HOWARD

### Analytical Chemistry of Molybdenum

By A. I. Busev. Translated from the Russian by J. Sohmorak. (Analytical Chemistry of Elements Series.) Pp. vi+247. (Jerusalem: Israel Program for Scientific Translations; London: Oldbourne Press, 1964.) 96s.

A. I. BUSEV has set out to give a critical survey of the whole of the analytical chemistry of molybdenum. He has used his own experience as much as possible to decide the relative merits of the methods, and has, I think, succeeded very largely in 'separating the sheep from the goats'. After a comprehensive account of the chemical and analytical properties of molybdenum, chapters follow on the detection and isolation of the metal. Further chapters on gravimetric, titrimetric, photometric and other methods for the determination of molybdenum take up the second half of the book. There is a very extensive combined bibliography and author index. The omission of any reference to Granger's aqueous *n*-butanol dithiol method for the photometric determination of molybdenum (*Analyst*, 83, 609; 1958) is, therefore, surprising. Not unnaturally, the author appears to be strongest on the Russian literature and this does have its advantages.

One cannot detect that the book is a translation, so well has it been done, and the text is remarkably free from errors. It is very well produced, and should be of considerable value to anyone whose work involves molybdenum.

E. J. DIXON

## SIGNS OF LIFE

## CRITERION-SYSTEM OF EXO BIOLOGY

By PROF. JOSHUA LEDERBERG

Department of Genetics, Stanford University School of Medicine,  
Palo Alto, California

THE imminence of interplanetary traffic calls for systematic criticism of the theoretical basis and operational methods of 'exobiology', the initial search for and continual investigation of the life it might encounter. Very little science is totally irrelevant to it, and the policy-maker must face a riot of potential approaches to space flight experiments. By every standard, this is an epochal enterprise: a unique event in the history of the solar system and of the human species, and the focus of an enormous dedication of cost and effort. It requires a new perspective in experimental policy. The broader interfaces of *exo*-(Earth's own) biology, by contrast, permit its fruitful growth within the context of methodologies and instruments that can lag behind broadly established needs and imaginative possibilities. A system for orderly appraisal of the problem would rationalize the partition of labour, our only means of managing a complex problem.

Mars is our prior target. Our premised information is only: (1) terrestrial observation: *esobiochemistry*; (2) the implications of Mars being a 'terrestrial planet'; (3) a very small body of definite observational results. The choice of our first experiments must take account of a wide range of theoretical possibilities not yet narrowed by the experimental process. Over this broad reach, logical necessity rarely coincides with logical sufficiency. The most compelling inferences might stem from the least likely event. Our speculation will be narrowed and policy simplified by tangible information about any aspect of Mars, especially if it encompasses the variability of the planet's features in space and time.

## Evolutionary Stages and the Definition of 'Life'

Fundamental to all biological theory, *exo*- or *exo*-, is the evolutionary principle. As is now commonplace, we recognize the following stages in the Earth's history:

(A) *Chemogeny* (*organic chemistry*). The production of complex organic compounds by a variety of non-replicative mechanisms—the primitive cosmic aggregation, photochemistry of isolated atmospheres, thermal and spontaneous reactions of inorganically catalysed, previously formed reagents.

(B) *Biogeny* (*biology*). The replication of a specifically ordered polymer, DNA being the terrestrial example, which specifies the sequence of its own replicas, and of the working materials, like RNA and proteins, from which cells and organisms are fashioned. Random experiments of error in replication, and natural selection of their developmental consequences, result in the panoply of terrestrial life.

(C) *Cognogeny* (*history*). The evolution of the mechanisms of perception, computation, and symbolic expression and interpersonal communication, whereby tradition can accumulate, culture unfold.

Mars must be supposed to have had an initial history similar to Earth. To ask whether Mars has life is to ask how far has its *chemogeny* gone; how like and how unlike the Earth's; has its evolution passed through the biogenic (ordered macromolecular) stage? Then through the *cognogeny*?

In evaluating a complex set of possibilities it is helpful to find classifying parameters which can be scanned

systematically, if sometimes only implicitly, to generate a probability space. In this case, the evolutionary principle furnishes the parameter: chemical complexity.

The initial planetogeny and the consequent differences in physical and chemical environment determine the possible points of departure of the evolutionary processes. On these grounds, Jupiter must have special interest for comparative *cosmochemistry*; but it is still much less accessible to close investigation, and we have even less of a basis to predicate a homologous *chemogeny* there than we do for Mars. In so far as Mars does retain some environmental analogies to Earth we might at least predicate, for one branch of our analysis, that any Martian life is based on chemical linkages, predominantly  $-C-C-$ ,  $-O-O-$ ,  $-C-N-$  and  $-O-P-$ , which are barely stable in aqueous medium. We leave to hypothesis the extent to which the constructions from these and other radicals emulate terrestrial *biochemistry* at each level of complexity.

The cosmic abundance of these elements is relatively high, and there is every reason to believe that Mars is at least as richly endowed as Earth in them. If the initial budget of carbon has not, like that of the Earth's crust, been completely requisitioned by life, then what form will we find it in?

*Chemogeny* generates a vast mixture of products through the level of random macromolecules. Mars must have nurtured such chemistry, whether or not it had progressed to *biogeny*. A negative assay for organic materials would preclude biology, but could we believe such a result? It would properly be blamed on deficiencies in the particular sample. The positive assay, if it told something of the concentration and composition of organic molecules, would add to our understanding of Mars's development, and would contribute to our judgment of the life-detection problem. But it would not answer it. On the other hand, once life has appeared on a planet, it would dominate its organic chemistry—most carbon compounds would be witnesses of biogenic (or *cognogenic*) specificity. The cataloguing of organic molecules is a description of the consequences of evolution and must make up a large part of our effort.

## The Chemical Scan

To promise an actual complete scan of hypotheses of molecular complexity would be pretentious and witless, notwithstanding that a computer can now be programmed to visualize all the possibilities. However, the fantasy of such a scan is a constructive exercise in evaluation of evidence for life. For each chemical species the imagination of the specialist might be challenged to ask: (a) is there any information concerning the existence of this item relevant to scientific inference in exobiology; (b) what are my prior expectations on the distribution of this species, with and without life; (c) what other data could contribute; (d) how would the observation be interpreted from a terrestrial foray; (e) what special methods are available or could be devised to detect the species?

We might nurture a hope of turning up a special treasure, a rare example of a molecule which would reveal something about the evolution of the planet and help narrow our choices among the confusing array of possible

Fig. 1. Contingency space. The universe of possible observations  $I$  includes the overlapping domains  $B$  and  $C$ , the predictions of biogeny and chemogeny, respectively. The remainder is  $M$ , contradictions of these models, and possible consequences of cogency. Should this also be bounded?

targets. In practice this advantage does not materialize so easily, for the hope is false. Not that no chemical species is potentially informative; paradoxically, every one is.

Consider hydrogen. In terms of the simple Venn diagram (Fig. 1), most expected observations would fall in the region  $(B \cdot C)$ , that is, would be consistent with biogeny but not imply it. However, the sensible absence of hydrogen from Mars' surface would fall in region  $(-B \cdot C)$ , that is, virtually preclude life. But if we could produce no plausible physical model for the disappearance of hydrogen, we would have to reconsider the region  $(I - C)$ , that is, to ask whether the anomaly implies a biogenic or cognogenic sequestration of the element. On the other hand, certain microscopic distributions of H are hard to reconcile with any chemogenic model, and point to the region  $(B - C)$ , that is, an inference in favour of biogeny. This verges on morphology, but can still be formulated as molecular statistics.

On another tack, suppose a specimen consisted of pure protium,  $^1\text{H}$ , to the exclusion of deuterium,  $^2\text{H}$ . The price of pure protium on the terrestrial market hints at the obstacles to a chemogenic model. Apart from cognogenic activity, if a biogenic system were exquisitely sensitive to deuterium-toxicity it might evolve a discrimination against it.

The arguments have been laboured, but are quite typical of those that discovery of any other species would arouse.

### Entropy or Unlikelihood?

Given the evolutionary continuity of life and our understanding of the organism as a chemical machine, there can be no absolutely distinctive signature of life. Some conjunctions—like a planetary depot of protium—would be so unaccountable to our present model of chemical behaviour that we would feel obligated to postulate the operation of a goal-directed system (biogeny or cognogeny) rather than accept the improbability of such a conjunction by chance. This choice plainly depends on our freedom of choice of models. For example, our present knowledge of chemogeny permits a wide latitude of hypotheses as to the range of molecular species that atmospheric photochemistry might generate. Further developments in our knowledge of chemogeny or of the available chemical and physical resources of Mars might confer useful constraints on the data that might now be 'explained away' as chemogeny, and thus cannot yet make a crucial contribution to our search.

From terrestrial experience we judge that the occurrence of any of a number of compounds in high purity is a sign of life. Such deposits at a macroscopic level tend to signify cogency—a smelter, a chemical laboratory,

a communications cable, rather than biogeny—organic structure usually being built of microscopically defined components. Negentropy is a necessary, but not sufficient, sign of life. However, it can help filter out the most promising situations. Then only the details of experience or confident use of available theory can decide whether the eddy has a chemical-kinetic explanation or a bio- or cognogenic one. Lacking our experience, a Martian visitor might credit diamantane carbon to some mysterious biogenic function, inhibited by Y chromosomes; if he were cleverer, to the General Electric Co. He would need very special knowledge of the Earth to predict that diamonds would be found in the ground (and even more to understand why men dig them up, only so that women will wear them).

Kinetic instability in the context of local chemical and physical conditions is another clue. For example, cover of photosensitive pigments (witness terrestrial chlorophyll) requires special attention to the magnitude of plausible synthetic processes, atmospheric-chemical versus biogenic, by which their steady-state concentration could be maintained. Analogous reasoning would apply to compounds which are thermolabile in relation to the ambient temperature, or chemically unstable species which should reach equilibrium with coexistent oxidant. Do we see a forest fire? Then we must think of the efficient system of photosynthesis which will restore the steady-state vegetation. Top-heavy structures, which high-altitude reconnaissance could perceive even without resolving single trees, houses, or bipeds, likewise tell of kinematic instability, and in turn, some process to re-raise what must some time fall. But geophysics competes with biophysics, and we have to discriminate life from vulcanism and orogeny.

In sum, unlikelihood in terms of the chemogenic model gives weight to any finding as a datum for exobiology. It should be possible to quantitate chemogenic likelihood, essential if a datum is to be given a measured value in any decision-making programme. The resolution of the measurement need not be very high to make it still very useful in comparing disparate approaches.

In more general terms, biota have a high density of internal information: the root of our conceptual distinction between matter and life is the rich story that life can tell about itself, a plot the details of which we can scarcely deduce from our simple knowledge of the initial conditions. But there must be a plot, that is, the information must have some interesting pattern, or we would not distinguish a cell from the dislocations in a snowflake.

### Optical Activity

Many molecular species can contribute in an important way to our appreciation of life. *A priori*, we have a very limited basis to predict which species will be most cogent. We should, of course, give high, but not exclusive, priority to terrestrial prototypes like amino-acids and nucleotides. Fortunately, there is a generic classification of compounds which is relatively independent of detail of structure, yet should pervade a biogenic chemistry. This is optical activity.

The argument for logical necessity of net optical activity has nothing to do with optical rotation. It depends on the crucial role of the informational macromolecule in a definition of life. When tetravalent carbon is incorporated into macromolecular structure, each carbon stands a reasonable risk of being an asymmetric centre, of having a distinctive substituent on each of its four valences. Such an atom is subject to stereo-(optical) isomerism, and its orientation, D- or L-, must be specified if the macromolecule is to be fully ordered, more concretely, if it is to have a well-defined three-dimensional shape. Conversely, biogenic macromolecules, having ordered asymmetric centres, have the necessary information to discriminate among the isomers of monomeric substrates.

On Earth, where biogeny has dominated the statistics of organic molecules, we find that the ratio of D- to L-glucose residues is at least  $10^{14} : 1$ .

Logical sufficiency can also be argued. Chemical enantiomorphs should be generated in equal proportions except under the influence of a catalytic system which is already asymmetrically organized. The global organization of a planet into one catalytic system of particular orientation is a catastrophe of a magnitude unique to biogeny. Spontaneous resolution might occur locally. Hence this criterion has its greatest weight when applied to a species which flows through the planetary circulation. A paragon would be labile molecules condensed from the atmosphere: optically active smog.

Within the biogenic system, both enantiomorphs of a metabolite might be generated, but this would be in precisely equal amounts with no greater likelihood than any two species designated at random. Chemogeny and sterically ordered biogeny thus give sharply contrasted expectations on these statistics, and biogenic chemistry can hardly avoid becoming sterically ordered.

These lines of inference do not account for such parochialisms as the undeviating series of L-isomers of amino-acids in esobial proteins. For example, D-alanine would be at least as interesting as L-valine in expanding the homologues of glycine. But, for that matter, why is  $\alpha$ -amino butyric acid passed over? We may know better when the rules of polypeptide conformation are better known; more likely, from the details of evolution of amino-acid anabolism and problems of discrimination among analogues. It is precisely at this level that the local biological theory fails, and thereby points to the crucial issues of a cosmic biology.

In view of the theoretical generality and historical tradition of the Pasteurian principle, it is paradoxical that the direct measurement of optical activity is weak by comparison to other instrumental approaches. However, the basic criterion is not optical rotation but molecular statistics. Enantiomorphs can be assayed with optically active reagents to give resolvable diastereo-isomers, and exploit the most sensitive methods known to chemistry.

### Macromolecules

Informational macromolecules define the boundary of chemogeny and biogeny, of chemistry and life. Their description on another planet is the fundamental challenge of exobiology. Replication of macromolecules (genes) and the inevitability of random error (mutation) open the door to natural selection and the evolution of more and more complex forms of life. A random polynucleotide is not life; routes to its photochemical-synthesis from simple gases and inorganic phosphate are in sight. Can we deduce the replication of a polynucleotide by any means short of the most recent achievements of direct observation and *in vitro* enzymology? Historically, we could deduce the informationality of macromolecules just from compositional data. When the same sequence occurs in many molecules—as in a sample of crystalline haemoglobin—we have to invoke an informational process to programme and implement the synthesis of the protein. In fact, only recently and rarely could we gain complete specifications of an actual sequence. This is usually inferred from fragmentary analyses of a fraction found to be monodisperse on a few measures and then assumed to be sequentially homogeneous.

The sequence need not be the gene itself. Macromolecular sequencing is also manifest in gene products, RNA and proteins. It is important that the sequence imply ordering from a template which selects from an abundance of kinetically equivalent choices, not merely a pattern inherent in the chemistry of the monomer, as in crystallization.

Molecular esobiology faces the same methodological problems. This challenge gives us the groundwork for

exobiology and assures that any instrumental advances will have redoubled utility. But it is a chastening note that biochemistry has barely reached the point of affirmation that antibody  $\gamma$ -globulin has an informational sequence or is specified by a polynucleotide. That this abundant and medically important molecule can still be so controversial must evoke some humility in our postulations and experimental efforts concerning macromolecules on another planet.

### How We Detect Informational Macromolecules

(A) *Compositional analysis.* (a) Does the sample contain macromolecules? (b) What is their composition? (c) Any evidence of informational ordering?

Esobiology is firmly founded on the isolation of macromolecular species and their purification before attempts at analysis. Some of the most successful methods are empirical recipes of extraction and precipitation.

More rational techniques include diffusional properties of large molecules, free diffusion, sedimentation, dialysis, molecular sieves, and electrophoresis, in principle also vapour phase diffusion (to remove monomers)—molecular distillation, gas chromatography and mass spectrometry. Solution chromatographic methods may also rely on the coincidence of functional groups on one molecule, for example, a polyelectrolyte.

Similar principles underlie non-separative methods of detection which have not been extensively developed to date. Rotational relaxation times can be measured by flow or electric birefringence, or the analogous polarization of fluorescence. Polyfunctionality is tested by intermolecular interactions of adsorbed dyes (for example, optical shifts in acridine orange on DNA) or the monomeric units with one another in special cases (hypochromicity of DNA, diagnosable on heat-denaturation). More direct chemical tests for polyfunctionality also suggest themselves.

The previous methods, in so far as they lack perfect generality, may give only a clue as to the composition of the macromolecule, as well as its molecular size. At the other extreme, we would seek the complete primary structure to emulate the recent *tours de force* of chemical technique. Reasonable inferences might be drawn from less complete evidence of structural individuality, hard to evaluate in advance: homogeneity in molecular weight or end-group analysis, crystallinity, or sharp fractionation by any other procedure. A sharp X-ray diagram of a heteropolymer sample could imply its individuality long before it had yielded to full analysis.

Other partial measures of great utility include the isolation of the polymer by specific reagents, especially enzymes, to give a pattern of characteristic fragments (the polypeptide 'fingerprint').

The underlying generalization is 'molecular speciation'. Chemogenic synthesis of macromolecules should generate a continuum of nearly equiprobable forms. Biogeny chooses a few of these and generates a sharply discontinuous polydiscrete spectrum, that is, it speciates. Speciation can be discerned by many measures, for example, the distribution of molecular weight. Thus a sample under analysis by a sophisticated instrument might reveal a sac of haem-polypeptide, containing about a billion (a thousand million) atoms of iron. Virtually all the iron-polypeptide consists of a single species, that is, almost all the molecules have 2,936 carbon atoms, no more, no less. After removal of iron and porphyrin, equal numbers of sub-units containing just  $C_{211}$  and  $C_{711}$  are assayed. It would be difficult to escape an allusion to life after a single encounter with the red blood cell that has just been described.

(B) *Functional analysis.* The adaptive values, the uses that biology has discovered for some species of macromolecules, reveal short cuts to their singularity. These functions are all reducible to a structural specification:

Function	Complex with	Example
Auto-replication	Inert polymer (same species) and polymer-building monomer	DNA: DNA + deoxynucleoside triphosphates
Hetero-replication	Inert polymer (different species) and polymer-building monomer	DNA: RNA + nucleoside triphosphates
Morphogenesis: fibres, membranes, vesicles	Formed polymer, similar species	Collagen: collagen sub-units
Enzyme	Substrate—catalytic effect Cofactors—to form holo-enzyme Analogues—complexes Inactive, <i>pro</i> enzyme	
Neutralizing	Whatever	Antibody: antigen, that is, any chemical species foreign to the reacting organisms
Transport	Hormones, toxins, nutrients	Serum albumin: hormones, toxins Permeases: nutrients and metabolites for transport in and out of cells

the stereospecificity of the polymer in reacting with other molecules.

In this list, the enzymatic functions are particularly promising in the light of their specificity and amplifying capability. Many enzymes have turnover numbers of  $10^4$  substrate molecules/sec/enzyme molecule. If suitable precursors (nutrients) can be defined, integrated enzyme-sequences or metabolic systems, like respiration or photosynthesis, extend the versatility of this approach.

The simpler the level, the more likely are we to find a metabolic analogue on Mars, for example, for the assimilation of elementary nutrients, C, N, O, S or P, into organic molecules. The next more complex molecules,  $H_2O$ ,  $CO_2$ , and  $O_2$  and  $NH_3$ , are the most pervasive metabolites of terrestrial life, and the choice among them for searching for evidence of their conversion into other compounds will depend mainly on instrumental considerations. In general, the more complex the metabolite being tested, the less our prior expectation that it was part of an extraterrestrial biogenic system. However, the complete system offers the largest amplification—a single bacterium could grow and multiply into tonnage masses in a few days, but might make the most exacting demands of the environment.

### Morphology

Biogeny rapidly elaborates higher forms of organization: cells, tissues, organisms, populations, which might be recognizable according to their own forms and to their rectifications of the environment. However, what systematic rules distinguish biological forms in general? Some forms are recognizable, for example, a friend's face, and recognition then contains many bits of useful information. Compound vesicles, apparent cells, are most inescapable in morphogenesis; their absence would at least set an upper limit to the stage of biogeny. Their presence would be extremely provocative, but properly would raise many scepticisms of chemogenic artefact. Nevertheless, esobiology has so many roots in morphology that we could scarcely ignore the insights that our historic practice of it would offer. Any recognizable forms would provoke tangible and hence useful working hypotheses of the Martian system.

Some aspects of morphology can be systematized. As an example which might illustrate speciation, ultrastructural spacings in the range of 20–500 Å could be detected by powerful optical (electron microscope, X-ray diffraction) as well as separative techniques. Approaches so cogent to esobial ultrastructure must play an important part in exobiology. Unfortunately, we have little empirical basis to prejudge the morphological detail that might be exhibited by an infra-biogenic planet, since so much of the chemical diversity of Earth has been pre-empted by life.

As is well known, five-fold symmetries are anathematic in crystallography. Hence, regular pentagonal and

dodecahedral forms might occur as elementary units, for example, perhaps a ferrocene, but no simple law of crystal growth could account for their occurrence in diverse sizes. A glen of periwinkles has a deductively simple signature of life.

### Signals

So far I have tacitly assumed that whether or not Mars has achieved biogeny, it has not passed to cognogeny. Reaction to the once notorious Schiaparellian *canals* may account for a position which has no rigorous basis. True, we have had no scientifically admissible sign of intelligent activity on or communication from that planet. However, we can only fancy whether an exotic culture would have either the means or the motive to effect recognizable communication. We can generalize that the works of cognogeny would constitute the most startling unlikelyhoods, exceptions to biogeny and chemogeny alike.

It is no trivial exercise to speculate how we could most compactly summarize our scientific culture. For example, a description of DNA and our amino-acids could portray the convergence of physical and chemical ideas in biology, and some of the least predictable aspects of esobiogeny. If we could but do it, a detail of the inter-neuronal synapse and the cytoarchitecture of the cerebral cortex would go even farther. How much of our cognogeny would then be deducible from these facts and our awareness of them?

Purposeful emissions cost enough more than mere listening that we do not undertake them ourselves, but we have made casual efforts to hear them. Further, we might hope to eavesdrop on the internal communications of another planet, perhaps more likely far beyond the solar system. Among other difficulties, efficient information is, by definition, indistinguishable from noise to the unbrieffed eavesdropper.

While a rigorous answer to any notions of Martian intelligence is difficult, a realistic policy is not. Cognogeny would reveal itself in divers ways, and, at least for Mars, we have no better recourse than to keep eyes, ears and noses alert for any signs of it as we make progressively closer approaches to the planet.

### Instrumentation

The rational classification of existing instruments, or those proposed for analytical purposes, is a task as difficult as it is urgent. The real aim, a classification of possible instruments, requires a total knowledge of physics, and some system for classifying this information that will help us to understand the relationships among existing instruments and suggest new ones. A proposed scan parameter is the energy-level of the transition by which the molecule is recognized. Further parameters include whether photons are introduced or emitted, whether chemical reagents are employed, including auto-reactions, whether the displacement or state of the analyte and of the probe is diagnostic, and, for radiation probes, the role of power, polarization, phase, wave-length, or flux vector of the probe. The first step in a detailed rationalization is to determine whether any more dimensions are needed for our matrix of possible configurations.

Radiation probes are usually limited, either in selectivity—say, absorptiometry, or sensitivity—say, nuclear magnetic resonance—but they have special value in conjunction with chemical reagents. Absorption (power loss) measurements have dominated instrumental analysis. Conventional optical methods rarely stabilize or measure input power better than 1:1,000, with corresponding limitations to detectivity. For example, optical molar absorptivity rarely exceeds  $10^4$  so that  $10^{-6}$  molar solutions ( $6 \times 10^{13}$  molecules in a  $1\text{-cm}^2$  cell) would give the lowest useful signal under the most favourable conditions. By contrast, fluorometric measurement (which can

## Structural Synthesis of High-Accuracy Automatic Control Systems

**M. V. Meerov**

**Contents:** Initial information and some characteristics of the *D*-decomposition curve; Systems with one controlling quantity; Systems with several stabilizing devices; Structural conditions of quality; Some non linear problems; Some numerical relations, Systems with several controlled quantities.

International Series of Monographs in Automation and Automatic Control, Volume 6

368 pages/July 1965 100s./\$15.00

## Linear Network Theory

**G. I. Atabekov**

**Contents:** Basic definitions and concepts; Basic relationships in sinusoidal current circuits; Network reduction and transformation; Methods of solving networks; Loci method; Two terminal networks; Four-terminal networks, Resonant circuits. Filters; Circuits with distributed parameters; Nonsinusoidal periodic waves (Fourier series); Transient analysis (classical method); The Fourier integral; The Laplace transformation.

648 pages/July 1965 90s./\$15.00

## Elements of Theoretical Mechanics for Electronic Engineers

**F. Bultot, Chargé de Cours, Institut National de Radio électricité, Brussels**

**Contents:** Vectors, vector systems, vector functions; Kinematics of a point; Dynamics of a free point; Centre of mass, dynamics of a point constrained in a circular trajectory, moment of inertia; Vibrations and waves, Scalar and vector fields; Statics.

256 pages/July 1965 45s./\$7.50

## Wholes and Parts— A General Theory of System Behaviour

**Oskar Lange, Professor of Political Economy, Faculty of Political Economy, University of Warsaw**

**Contents:** The active element; Coupling of active elements; The system of active elements and its structure; Systems of higher orders, How does the system act?; The process of development of the system Equilibrium and stability; Ergodic processes; Self steering, The dialectical character of development.

80 pages/June 1965 30s./approx \$4.50

## Semiconductor radiation detectors have grown up

In conjunction with A.E.R.E. Harwell a wide range of solid state radiation detectors have been developed and are now in routine production. Sensitive areas from  $0.6 \text{ cm}^2$  up to  $50 \text{ cm}^2$ , high resolution models for spectrometry and large area detectors for monitoring are available. Both alpha and beta sensitive detectors as well as the recently developed transmission models with depletion depths up to 1 mm are currently being manufactured. Thus, the full advantages of semiconductor engineering are now a practical proposition for a great number of radiation projects. Write for general brochure and data sheets on current types to:

exploit shifts in wave-length, flux vector, polarization and phase) can easily measure  $10^4$  molecules and can be extended at least to  $10^6$ . The delicacy of excitation methods (which could also include chemical, nucleonic and thermal excitation) stems from the measurement of the data signal merely against a detector noise background as compared with the much larger power fluctuations of practical probes.

Optical activity is also usually measured via loss of power (attenuation of polarized light by a crossed analyser): the molar rotations are relatively small, present detectivity being about  $10^{11}$  molecules. If some method of transforming optical rotation to an excited signal were developed, it would enormously enhance the power of this technique.

The most sensitive approaches to analysis are two-stage mechanisms: the selective displacement of the analyte, then a sensitive detection. In principle, such methods might detect a single molecule, as in mass spectrometry: selective  $m/e$  displacement followed by the sensitive detection of an ion that can be accelerated to arbitrary energy. The potential information content of a mass spectrum is especially high since the theoretically measurable mass of a single molecule is defined to a resolution far better than  $10^{-6}$ , independent of the variety of energetic states, which broaden other physical features. Existing instruments still lag behind theoretical limits of mass resolution; yet have already demonstrated their power in organic analysis. Further, the mass datum at high resolution for an intact molecular ion is deductively reducible to a molecular composition, unlike the inferential data given by most other spectroscopic techniques, and the statistics of the fragments also give detailed insight into the complete structure of the molecule. From these considerations the combination of a mass spectrometer with a simple, rugged, separative device, like the gas chromatograph, promises to be the most powerful component of analytical systems for biochemistry. However, a science of metrology, the orderly study of methods of measurement, remains to be developed. I can have little confidence that the last word has been said on this issue.

### Some Private Thoughts on Exobiological Strategy

The multitude of possible means and detailed ends in exobiology leaves little hope that a brilliant flash will

illuminate the whole picture as a happy substitute for the diverse paths of exobiology. Nor should there be any discouragement of the variety of talents and insights that would be needed in any event for the full development of the subject. The overriding problem in planning is, of course, how little we actually know about surface detail and atmospheric composition of Mars. We are also bedevilled by the uncertain hazards, but immense stakes, to either planet of an intemperate rupture of the inter-planetary barrier. Earth-based telescopes can, to be sure, add significantly to our present appreciation of Mars, and hence of the hazards of landing. But the next significant step would be a Mars-orbiting observatory, keeping the planet under a constant synoptic scrutiny from a safe distance, close enough to measure significant surface detail, and large enough to maintain the most sophisticated instrumentation, telemetry to Earth, and perhaps even some Earth-based regulation of its surveillance schedule and precautions against accidental intact landing.

Such an approach to Mars would also open the way to political agreements to unify terrestrial strategy and can allow constructive co-operations like the International Geophysical Year of recent history, for example, to facilitate the relaying of synoptic data. While it is essential to mount vigorous instrument development efforts to assure that a landing can ever be implemented, the detailed specifications of experiments should take full advantage of the most up-to-date planetological information. That is to say, the final decision to implement a landing on Mars should be suspended until we can have digested the data from a Mars orbiter. This criterion lends further weight to the strategy of designing a general-purpose laboratory for planetary investigation, in which many investigators can participate, and which has the flexibility to be readily reprogrammed in the light of new data. At present, for a biologist to participate actively in space research requires a commitment to engineering efforts which few are willing to undertake.

The deliberate staging of the exploration of Mars, perhaps with international agreement to proceed first with reconnaissance while preparations are made for comprehensive landed missions, would allow for the widest participation of interested scientists, both in the design of experiments in exobiology and in the prudent determination of global policy for the solar system.

## DEFINITION AND USE OF ZEBU, BRAHMAN OR *Bos indicus*\* CATTLE

By PROF. JOHN FRANCIS

Department of Preventive Medicine and Anatomy, Veterinary School,  
University of Queensland, Brisbane, Australia

THERE has been a steadily increasing interest in Brahman cattle and their hybrids in Queensland during the past ten years. This has been due to their resistance to ticks and general ability to thrive better than British breeds under the various stresses of a tropical environment<sup>1-3</sup>. These facts, and anatomical investigations of British and Brahman cattle<sup>4</sup>, stimulated our interest in zebu cattle in various parts of the world.

In trying to determine the boundary between zebu and other cattle it was surprising to find that no real definition or concise description of the characteristics of 'a zebu', or of the apparently precise binomial *Bos indicus* (literally Indian ox), could be found. Linnaeus<sup>5</sup> described it as "a bovine whose horns are shorter than its ears, that has a

humped back and no mane"—the latter probably distinguishes it from *bibos*. Grasse<sup>6</sup> is scarcely more precise. Zeuner<sup>7</sup> has given much the most satisfying account of the origin of cattle, although his description of the zebu is not in complete accord with the definition proposed here. He says: "That the primigenius breeds came from temperate or western Asia is evident from the distribution of their wild ancestor in these parts". He discusses interesting breeding experiments in Europe during which these early animals were "reconstituted", and reports that they not only had the physical characteristics of the aurochs but also their agility and wildness. He describes the zebu as "characterized externally by a prominent hump on the shoulder, a long face, usually steeply upright horns, drooping ears, small brow-ridges which give it a peculiar expression, a dewlap and slender legs. Its colour varies, but is commonly of the grey type varying to white or black. Many crosses have occurred between

\* It is considered that these three terms are practically synonymous, but the name Brahman tends to be reserved for a particular type of zebu developed in the U.S.A. In some of the old Australian and other reports the name Brahman is used which doubtless originated from the sacred Brahmin bulls of India<sup>11</sup>.

zebu and *primigenius* breeds, especially in Africa, and these should be left out of consideration . . . the zebu with its long face, steep horns and hump is so distinct an animal that its origin has been discussed frequently".

Zeuner<sup>7</sup> discounts the possibility that the zebu could have derived from a cross between *primigenius* and *bibos* species and relates that the first archaeological record of the zebu is about 4500 B.C. Both *primigenius* cattle and zebu appear on Indian seals of 2500 B.C. and, allowing for some artistic licence, the zebras on these seals have the main characteristics of the modern Brahman. He<sup>7</sup> accepts the very early separate origin of the zebu, probably from the wild *Bos namadicus* of India or some region to the west of India, and says that this would make it possible to understand why there is a specifically tropical breed of cattle present from the earliest times onwards, and now distributed from China to Africa, with India as the focus. The sculptures and hieroglyphics of Egypt show three different types of *primigenius* cattle, and from about 1570 B.C. onwards zebras are also frequently shown. The earliest record in Palestine is in the ninth century B.C., and zebras then became well known all over the eastern shores of the Mediterranean. "They never succeeded, however, in ousting *primigenius* and longifrons breeds in the rest of the Mediterranean littoral, presumably because humped cattle were climatically unsuited to non-tropical countries".

Zeuner and Mourant<sup>8</sup> propose a nomenclature for the Bovinae. The first species listed is *Bos (Bos) primigenius* Bojanus (wild European aurochs, extinct since 1627). *Bos taurus* is described as *Bos (Bos) primigenius* f.d.\* *taurus* Linnaeus (domestic humpless cattle of Europe, type locality Sweden), and *Bos indicus* as *Bos (Bos) primigenius* f.d. *indicus* Linnaeus (domestic zebu, type locality China). The foregoing name for *Bos indicus* can scarcely be regarded as suitable because it is generally accepted that this species or sub-species arose from the wild cattle of India, *Bos namadicus*, and the zebu is clearly not the "forma domestica" of the European *Bos primigenius*. Why China is given as the type locality is also difficult to understand, as all the evidence indicates that India is the origin and focus of zebu cattle. Zeuner<sup>7</sup> says that cattle reached China from the west and south-west, and he clearly uses the term "primigenius breeds" to exclude *Bos indicus*.

The name, *Bos (Bos) namadicus* f.d. *indicus* (domestic zebu, type locality India), is suggested as the most suitable name as it is felt that it accords well with Zeuner's statement that "there is a specifically tropical breed of cattle present from the earliest time onwards, and now distributed from China to Africa, with India as the focus".

The descriptions by various authors<sup>9-13</sup>, and my own observations in Australia and Africa, lead to the following tentative definition of a 'typical zebu'†, or *Bos indicus*: A bovine with a well-developed musculo-fatty thoracic hump and dependent dewlap. In the male the prepuce is pendulous and in the female the umbilical fold well developed. It has a coat consisting largely of straight medullated hair fibres and the sweat glands are larger and more numerous than in *Bos taurus*. The thoracic spines are bifurcated and the caudal vertebrae do not extend into the distal portion of the tail covered by the switch. (The fact that the thoracic spines are a variable characteristic for intermediate type cattle does not reduce the value of the differentiation from *Bos taurus*.)

The shape and size of the horns are considered to be unimportant as they may vary enormously, and typical zebras may be polled. Some authors have placed considerable emphasis on the long narrow skull as being characteristic of the zebu, but again this can scarcely be accepted, as the gir, which must be regarded as a zebu, has a broad, domed forehead<sup>11</sup>. This breed and the Kankrej, so well illustrated by Olver<sup>14</sup>, are probably

\* *Forma domestica*.

† Henceforth zebu, Brahman or *Bos indicus* refers to a 'typical zebu'.

responsible for the head characteristics of the American Brahman<sup>11</sup>. The ears, although generally large and dependent, also vary much in shape and size.

It should be added that the term 'thoracic hump' is ill-defined. As used by Kelley<sup>11</sup> and Mason and Maule<sup>12</sup> the definition appears to depend on external appearance and applies to a hump which is more or less squarely above the forelegs. On the other hand, Epstein<sup>10</sup> defines a thoracic hump as one developed from the thoracic, as distinct from the cervical, portion of the m. rhomboideus. On the former definition the American Brahman cattle have a thoracic hump as well as many other zebu characteristics. However, limited dissection by Butterfield (personal communication) shows that their humps are developed from the cervical portion of the m. rhomboideus. Nevertheless, they extend caudally as far as the fifth thoracic dorsal spine, a limit not exceeded in photographs of bisected Boran cattle kindly supplied by H. P. Ledger of Kikuyu, Kenya. The fatty surface of the bisected hump has led many people to conclude that the hump consists almost entirely of fat; but dissection in Queensland, and inspection of photographs from transverse sections of humps supplied by H. P. Ledger, show that there is a considerable amount of muscular tissue, particularly in the anterior portion. In this article it is the external appearance of the hump which is used as a guide in distinguishing thoracic from cervical humps, although further work may permit a more satisfactory definition. Some authors have suggested that there are

Fig. 1. Young Brahman bull of American descent from Cherokee stud, Queensland. This bull shows the broad forehead and good beef qualities typical of the breed.

Fig. 2. Champion Boran bull, Nairobi, Kenya. This bull is from the fine herd developed by Mr. W. D. Hinde, of Nanyuki. In addition, with the aid of artificial insemination, he has developed an outstanding herd of hybrid cattle which are about five-eighths Boran and three-eighths Red Poll. The cows are milked in corrals as well as raising a calf.

zebu cattle with no hump, but they do not specify the breeds or other characteristics of these animals, and the expression 'humpless zebu' would seem to be a contradiction of terms.

The American Brahman (Fig. 1), the Boran (Fig. 2) and the Kankrej<sup>14</sup> may be cited as examples of cattle with typical thoracic humps, and Africander and numerous hybrid cattle as animals with cervico-thoracic or cervical humps. The hump is, of course, best seen in the uncastrated male, and Jersey or Angus bulls may have as much crest or cervical hump as some African or Indian cattle.

The zebu has a characteristic voice and temperament well described by Kelley<sup>11</sup>. The temperament *vis-à-vis* the British breeds of cattle may be loosely compared with the difference of temperament between the alert or fiery thoroughbred and the heavy 'cart horse'. When properly handled by their attendants, zebu cattle may be quieter and more co-operative than British cattle; but this does not alter their characteristic lively temperament under different circumstances and, in my experience, temperament is broadly similar in all zebu cattle including the Sahiwal and American Brahman, and I regard these cattle, and probably all those included in group 2 of Mason and Maule<sup>13</sup>, as coming within the definition of zebu.

As might be expected, Youatt<sup>15</sup>, with his great powers of observation and descriptive ability, excellently portrayed the general characteristics of the zebu, and Fig. 3, reproduced from his book, shows a zebu which was the 'Nagore' bull exhibited at the Christmas Cattle Show in London in 1832, together with a cow of the same breed. (The prize carcass at Smithfield in 1848 was from a zebu × Ayrahire.) "They were beautiful animals and attracted much attention. . . . They are not buffaloes, but of the highest breed of Indian cattle. They are used in India by the higher orders, to draw their state carriages, and are much valued for their size, speed and endurance and sell at very high prices. . . . They will travel, with a soldier on their backs, 15 or 16 hours in the day, at the rate of six miles an hour. Their action is particularly fine—nothing like the English cattle, with the side-way, circular motion of their hind legs—the Nagore cattle bring their hind legs under them in as straight a line as the horse. They are very active, and can clear a five-barred gate with the greatest ease. Mr. Perkins has a calf which has leaped over an iron fence in order to get at the water, and when he has drunk his fill, leaps back again. . . . The bull is employed in a light cart, in various jobs about the farm: sometimes he goes fore-horse in the waggon-team, to deliver corn; he also drags the bush-harrow, and draws the light roller over the ploughed land. He is very docile and tractable, when one man drives him, and attends upon him, but he has now and then shown symptoms of

dialike to others. . . . He is very fond of being noticed; and often, when he is lying down, if any one to whom he is accustomed goes and sits down on him and strokes him over the face, he will turn round and put his head on their lap, and lie there contentedly as long as they please." The latter part of this quotation perfectly portrays the temperament of the Brahman.

The descriptions of African and Asian cattle show that there are innumerable gradations and variations between the zebu and non-humped cattle. Some of these have been designated as types or breeds, and there is much discussion concerning their origin. This is doubtless justified; but the varied and extensive crossing with the British breeds, following the introduction of 24 Brahman bulls and 25 females into Queensland between 1933 and 1954 has produced almost all the types of conformation (excluding horns and the very dwarfed breeds) illustrated in the articles and books mentioned here.

It is therefore possible that all the various intermediate types have derived from crosses between the zebu, which originated in India or some adjoining part of Asia, and non-humped cattle; and Curson and Thornton<sup>8</sup> (p. 621) do state that the Sanga cattle, so widely distributed in Africa, originated by the intermixture, probably in Egypt, of the Hamitic longhorn and lateral-horned zebu types.

Mason and Maule<sup>13</sup> divided the cattle of Africa into: Group 1, Sanga; Group 2, zebu; and Group 3, intermediate; but both groups 1 and 3 could be regarded as intermediate between *Bos indicus* and *Bos taurus*. Distribution of blood groups or haemoglobin types<sup>16</sup> may throw further light on the origin and classification of various types of cattle, although the presence of certain blood groups is not necessarily more significant than anatomical or other general characters.

Kelley<sup>11</sup> has dealt with the 'average characteristics' of the various hybrids, and some cattlemen in Queensland consider they can assess quite accurately the amount of 'Brahman blood' in an individual by its conformation and other characteristics, and that this is broadly related to hardihood and disease resistance. The Africander cattle in Queensland are considered to have anatomical and other characters similar to those of an animal with three-quarters Brahman 'blood' and one-quarter from a British beef breed. Differences of one-quarter Brahman 'blood' can be easily recognized on inspection, and experienced cattlemen distinguish one-eighth amounts of Brahman 'blood' in hybrid cattle, but this can scarcely be very accurate.

Discussing the results of dissecting various British breeds of cattle and Brahman crosses, we<sup>17</sup> concluded that, contrary to general belief, there was no difference between the various breeds, in the proportional distribution of the different 'muscle groups' based either on weight or on economic value. In the recent past there has been a trend to produce quickly-maturing cattle and to consider that the larger, later-maturing cattle lacked 'quality'. But it is evident from the foregoing results that the latter types of cattle, whatever their breed, can be used with confidence that there will be no deterioration of muscle-weight distribution.

The beef industry of tropical areas must be based on cattle well adapted to the local environment, and from the point of view of muscle-weight distribution there can be no reason for rejecting adapted cattle, no matter what their conformation, from areas where they are established. There has been much difference of opinion concerning breeding policies in tropical countries, but zebu cattle are considerably more resistant to most diseases than are cattle of European breeds<sup>18</sup> and, after a careful survey, Faulkner and Brown<sup>19</sup> expressed considerable doubt concerning the use of European breeds for improvement in the tropics.

Leaving aside dairy cattle, which can be kept under special conditions more suitable to the high-yielding

Fig. 3. A Brahman bull in England about 1830. "He is very docile and tractable when one man drives him." (From ref. 15)

European breeds, the only modification to the foregoing opinions would be that a judicious infusion of European 'blood' may introduce desirable characteristics to some local breeds. This has become much easier with the development of artificial insemination, and it is now realized<sup>1,2</sup> that the stabilization of suitable hybrid cattle is far easier than had been supposed. Thus, over much of Queensland, which stretches from latitude 29° to 10° S., the best adapted hybrids will probably vary from three-eighths to five-eighths Brahman 'blood' and it is very unlikely that there will ever be large commercial herds of pure Brahmans. In the same way, suitable experiments and observations could lead to decisions concerning the correct admixture in other tropical areas, and this could move more towards the European breeds with improvements in disease control and agricultural practice.

I thank Dr. R. M. Butterfield for his advice, and the Australian Cattle and Beef Research Committee for financial support.

## SEEING IN DEPTH

By R. L. GREGORY

The Psychology Laboratory, University of Cambridge

EYES are biological early warning systems. By giving information of events distant in space they serve to probe the immediate future, allowing brains to transcend simple reflexes and control strategic behaviour. Without information of distant objects there can be no anticipation of danger, no organized attack, no knowledge of the world. Indeed, the development of brains must have depended on seeing in depth.

The brain has a most difficult task interpreting retinal information from distant objects. The retinal image has lost a dimension: somehow the brain must construct depth from the projection of three dimensions reduced to two. For near objects the different views of the two eyes are used to compute depth, but the base line between the eyes is too small for distances beyond 50 ft. or so, when we are effectively one-eyed. With a single eye we generally see the world more or less accurately in three dimensions. For distant objects we use many 'clues' to depth, with a subtlety in the best traditions of the sleuth. With increasing distance, outlines look more blurred and fine detail is lost, objects look blue from increasing atmospheric haze, and more distant objects are in part hidden by those nearer the observer. These are some of the available clues to depth.

Fig. 1. The Necker cube. This spontaneously reverses in depth. There is no information available for deciding which is the nearer and which the further face. The perceptual system entertains first one hypothesis, then the other. The brain never makes up its mind!

Fig. 2. An impossible object. This cannot represent any possible physical object, for it has conflicting depth 'clues' (after L. S. and R. Penrose, *Brit. J. Psychol.*, 49, 31 (1958)).

One can see why perception of depth is so difficult by thinking about pictures. Although a picture is itself two-dimensional, it represents objects lying in three dimensions. But this is strictly impossible, and so pictures are essentially ambiguous in depth. Consider a drawing of a simple ellipse: Is the object represented distant and large, or small and near? Is it an elliptical object, or a circle tilted at an angle? The two-dimensional drawing could represent any of an infinite set of objects. Add shading, perspective—or an indication that it is a wheel—then we see one specific object. Visual ambiguity in depth is seen dramatically in figures which could equally well lie in more than one orientation. For example, Fig. 1: a flat drawing of a skeleton cube. A given face is seen first as the front, then the back. The alternative 'hypotheses'

are entertained perceptually in turn, and we never do see the figure as a unique unchanging object.

Pictures are not only ambiguous; they are also paradoxical. A picture is seen to be lying flat on its paper or canvas, and yet is also seen in three dimensions as indicated by its perspective and other depth cues. It is paradoxical in being seen as both flat and in depth at the same time. Conflicting cues to depth can produce 'impossible objects'. Fig. 2 cannot be an object lying in space. Fig. 3 cannot even be seen. In both cases, the trouble is over the third dimension.

Why should the eye accept a picture as representing objects lying in a space different from its own? It does so because a picture is essentially like a retinal image—both are flat projections of three-dimensional space. Pictures give simplified images, and very likely distorted in various ways, but the brain is so familiar with the problem of adding the third dimension from information given by the flat retinal image that we might expect it to cope with pictures. But there is an important difference between pictures and retinal images. Both are ambiguous, but retinal images do not lie perceptually in both two and three dimensions. We do not 'see' the flatness of the retina, or its texture: they are not signalled to the brain. Thus the brain has a more difficult task dealing with a picture than with normal objects. The textured background imposes a highly artificial problem to the visual system which it cannot completely solve. It is indeed unfortunate that experiments in perception have largely used figures drawn on paper. It is only when the double reality of the picture and what it represents is being explicitly investigated that pictures should be used in visual experiments.

It is, however, possible to produce pictures which, like retinal images, have no information of their flatness. This we may do by avoiding all background texture, and viewing with a single eye. When Fig. 1 is shown in this way—luminous, glowing in the dark—it appears as a truly three-dimensional cube. It still reverses in depth—it is still ambiguous—but it is no longer paradoxical in depth. The luminous figure looks different in another way—the apparently further face always looks larger than the apparently nearer face, whichever this may be. We see this distortion most dramatically in a truly three-dimensional skeleton cube, made of wire and coated with luminous paint to make it glow in the dark. The true cube also reverses in depth, and when it reverses it changes shape—the apparent front appearing too small. It becomes a truncated pyramid. Also, it rotates in the most odd way when the observer moves round it, but that is another story<sup>1,2</sup>.

Why should the luminous cube change shape when reversed in visual depth? This is answered by asking a silly-sounding question—why does a cube normally look like a cube? This needs some explanation, for since the

Fig. 3. This figure cannot even be seen. Again the difficulty is over the third dimension.

Fig. 4. The Müller-Lyer arrow illusion. Outgoing fins expand the shaft joining them, the ingoing shrink it. The 'fins' can be regarded as perspective lines of corners. When shown with no textured background (luminous) they look like true corners. The perspective depth appears to produce the illusion by triggering primary constancy scaling.

back face is further away, it must give a smaller image to the retina. But it does not look smaller—it looks the same size as the front. Although all objects give smaller retinal images as they recede from the eye, this geometrical shrinking is generally compensated by the brain, to give 'size constancy'. Size constancy was known to Descartes<sup>3</sup> in the seventeenth century, and has been investigated intensively since, notably by R. H. Thouless<sup>4</sup> in the 'thirties. It serves to give immediate recognition that a distant bottle is pint or half-pint, or whether it is a cat or a tiger about to spring. There are various theories about constancy<sup>5,6</sup>, but I believe it to be produced by an active scaling process in the brain, either set according to the apparent distance of viewed objects or set directly by various depth cues. We may call the underlying processes 'constancy scaling'.

When we see the skeleton wire cube distorted, when reversed in depth, we see our constancy scaling at work. But it is working backwards. For it is working according to the apparent and not the true depth of the object. Although constancy scaling normally corrects for the shrinking of retinal images with distance, reversal of depth makes the normally useful compensation distort visual space. The cube looks more distorted than it would if there were no constancy scaling correcting for the shrinking of the image with distance. These distortions occur whenever depth reverses in non-paradoxical figures. It could happen in real conditions, such as landing aircraft, or in space flight, and the consequences might be serious<sup>7</sup>.

### The 'Geometrical Illusions'

We know, then, that visual space is distorted when depth is seen wrongly. Can this somehow explain the distortions of the well-known 'illusion figures'? Fig. 4 shows the most familiar example: the outgoing arrow heads expand the line (or the space) between them, while the ingoing heads shrink it. Now these 'arrow heads' can be thought of as perspective drawings of corners lying in depth. They are the same shape as the retinal images of real corners<sup>8</sup>. With the outgoing arrow heads the vertical line would be distant, the heads representing, for example, the lines of the ceiling and walls of the inside corner of a room. The ingoing heads are perspective drawings of an outside corner, say, of a building or box, where the joining line would be near.

If the perspective features of retinal images do indeed serve to set constancy scaling, then when these features are present in flat pictures we must expect them to produce distortions of visual space. Constancy scaling corrects for shrinking of the retinal image with increasing distance, but pictures present perspective depth features with no

change in distance to compensate, since they are physically flat, and so the scaling must be inappropriate. We must expect objects indicated as further away to be systematically expanded<sup>9</sup>. This is just what happens, apparently for all the illusion figures, with people familiar with corners and parallel lines.

It has been known for sixty years that people who live in environments largely free of right angular corners and parallel lines—such as the Zulus, who live in a 'circular culture' of round huts—do not suffer these distortion-illusions<sup>10</sup>. Miss Jean Wallace and I found that a man of middle-age, who recovered his sight by corneal graft

after being blind since early infancy, was not subject to the illusions<sup>11</sup>. His perception of depth was also most odd. It seems that early experience of perspective features is important: apparently we learn to use perspective for setting constancy scaling.

Can we demonstrate experimentally a close connexion between depth and distortion illusions? There are several hints in the literature of such an origin of the illusions<sup>9,12</sup>, but there is a difficulty. It is always assumed that size constancy works simply according to apparent distance<sup>3</sup> (which is indeed true for the luminous cubes), but if this were always the case it could not produce distortions in figures seen as flat. But the illusion figures are generally seen as lying flat on their paper backgrounds, so how can we invoke constancy to account for these distortions?

### Measuring Depth In Pictures

The apparatus is shown in Fig. 5. The illusion figure is presented as a back-illuminated transparency. Light from it is polarized, and cross-polarized at one eye. Both eyes, however, view a small dim movable light which is optically introduced into the figure with a part-reflecting mirror. Now this light may be adjusted in distance, until it matches the apparent distance of any selected part of the figure seen with a single eye. The figure's depth is given by its perspective features, but the light's distance is given by convergence of the two eyes. Positions of the light are recorded on the graph paper at the top of the apparatus, and so we plot visual space in three dimensions, using the two eyes as a range-finder to measure the effect of perspective on a single eye. Fig. 6 shows how the arrow illusion is related to its apparent depth, as measured with this technique. The similarity of the distortion and depth functions, for various angles of the fins, demonstrates the close relationship we should expect—if indeed perspective features can set constancy scaling—to produce illusions when the perspective is inappropriate to true distance.

Fig. 5. Apparatus for measuring visual depth in pictures. The picture (for example, an illusion figure) is back-illuminated, to avoid background texture. It is seen monocularly, the light being polarized, and cross-polarized at one eye. The reference lamp (L) is seen by both eyes, by reflection from the part-reflecting mirror (M), and is seen as lying in the picture. Its distance is adjusted to equal the apparent distance of any selected feature of the picture. Positions are marked on the graph paper (G), giving a plot of visual space in three dimensions (Gregory and Townes).

Fig. 6. Full line shows extent of Muller-Lyer arrow illusion (measured by adjusting a 'neutral' line to apparent equality) for a range of fin angles. Figures presented without background texture, to a single eye. The depth (broken line) is the difference in apparent distance between the shaft and ends of the fins.

### Depth Optics

Can we improve instruments, or devise new instruments, for extending the eye's ability to see in depth?

The microscope is a direct extension of the eye, extending its ability to see the very small by effectively making it see objects extremely near. But when used at high magnification, its depth of focus is so small that structures lying only a few microns further or nearer the plane of sharpest focus are degenerated to be unrecognizable. It cannot provide the separated views to the two eyes to give stereoscopic depth. This limitation, however, can be overcome<sup>13,14</sup> by vibrating the objective lens of the microscope so that the plane of sharp focus scans rapidly up and down through the specimen, extracting the depth information with each scan. But if this were presented on a plane we would see confusion, for we would be compressing three into two dimensions. Somehow the information must be reconstituted into three-dimensional visual space. This can be done by projecting the image on to a screen kept vibrating in phase with the scan through the specimen. The image on the vibrating screen then changes systematically as it moves to and from the observer, and builds in the volume swept by the screen a 'solid image', magnified in depth. We can see, for example, brain cells magnified a thousand times in three

dimensions. In practice the vibrating screen introduces difficulties, but it can be replaced by a rotating helical screen, or a screen avoided altogether, by sweeping the pair of images in opposition across the eyes, in a way the observer's brain accepts as signalling depth.

Could we devise a way of drawing pictures in three dimensions? Do artists have to be for ever limited to flat planes on paper? The problem is to produce a pair of lines, one for each eye, produced under the control of the artist, so that correct stereoscopic depth is given by the horizontal separation of the lines. We have recently built just such a device. The depth artist holds a stylus, bearing a small bright light which is imaged on a pair of Thorn electroluminescent image-retaining panels. As he draws with the light, in three dimensions, glowing lines are presented to each eye and fused by the brain into a single picture in depth. He sees and creates in a

three-dimensional world, where artist and scientist meet.

## NEWS and VIEWS

### The Royal Society: S. G. Brown Award and Medal

THE Royal Society's S. G. Brown Award and Medal has been won this year by Mr. F. T. Bacon, consultant to Energy Conversion, Ltd., for his work in the development of fuel cells, on which he has been continuously engaged for the past twenty years. The award is made annually by the Council of the Royal Society, on the nomination in turn of the Institutions of Civil, Mechanical and Electrical Engineers, for an outstanding contribution to the promotion and development of mechanical inventions. The nomination is based on work carried out during the year of the Award and the preceding five years. The 1965 nomination was made by the Institution of Mechanical Engineers, of which Mr. Bacon is an Associate Member.

### Prof. A. C. Haddow, F.R.S.

THE cross of Chevalier de la Légion d'Honneur has been awarded to Prof. Alexander Haddow, director of the Chester Beatty Research Institute of the Institute of Cancer Research, London. This award is an indication of the esteem in which Prof. Haddow is held in scientific circles in France and is at the same time an expression of appreciation of much friendly collaboration over many years. Recently, Prof. Haddow has been closely associated with discussions about the international support of cancer research, in particular with the proposals put forward two years ago by the French Government.

### Space Research in the Ministry of Aviation:

#### Mr. J. G. Lewis

MR. J. G. LEWIS has been appointed director (space) at the Ministry of Aviation Headquarters in succession to Mr. C. J. Stephens, who is now attending the Imperial Defence College. Mr. Lewis was born in Skipton, Yorkshire, in 1921 and educated at Skipton Grammar School and later at Christ's College, Cambridge, where he specialized in mathematics and physics. In 1942 he entered the Air Defence and Research Establishment at Malvern (now the Royal Radar Establishment), where he worked on searchlights control and surveillance radars. In 1956 he attended the 17th course at the Joint Services Staff College. He was promoted to senior principal scientific officer in 1957 when, as superintendent of the Special Projects Branch at the Royal Armament Research and Development Establishment in Kent, he became more directly involved in the development of guided weapons. For the past three years he has been an assistant director in the Defence Research Staff in Washington, D.C., concerned with U.S. guided weapons and space activities and Anglo-American co-operative programmes.

### Psychology in the University College of Swansea:

#### Prof. C. E. M. Hansel

MR. C. E. M. HANSEL, who has been on the staff of the Department of Psychology in the University of Manchester since 1949, has been appointed to the newly established chair of psychology in the University College of Swansea. Mr. Hansel was born in 1917 and educated at Bedford School. From 1938 until 1946 he served in the Royal Air Force and reached the rank of squadron leader. After demobilization he proceeded to Fitzwilliam House, Cambridge, where he read psychology in Part II of the Moral Sciences Tripos. His principal research interests have been in the field of visual perception and, in particular, he has been developing a theory intended to integrate the physical and psychological phenomena of colour vision. In this sphere he is an authority. He has recently designed a new type of teaching machine. He has also excelled as the leading critic of the experimental basis of claims for extra-sensory perception. His thorough-going examination of this field of enquiry is to be published in the spring of 1966 (by Scribners, of New York) and will, no doubt, create considerable consternation among para-psychologists and their adherents. The topic will now be placed in its correct scientific perspective. While at Manchester, Mr. Hansel collaborated with Prof. John Cohen in researches into subjective probability, temporal phenomena, the spread of ideas, and other topics. This resulted in a joint book, *Risk and Gambling* (1956), and numerous papers on decision-making, the measurement of linguistic usage, and the kappa effect. Mr. Hansel is a talented musician, and for many years played first violin in the Alderley Edge Orchestra.

### Second Chair of Electrical Engineering in the College of Advanced Technology, Birmingham:

#### Prof. J. E. Flood

DR. J. E. FLOOD has been appointed to the second chair of electrical engineering at the College of Advanced Technology, Birmingham. He gained his initial education at the City of London School and then went on to take an engineering course at Queen Mary College. After war-time service at the Admiralty Signal Establishment, he joined the Research Laboratories of the British Post Office and for the next five years was occupied with the application of electronics to automatic telephone switching. Deciding to get nearer the product, he joined the then Siemens Brothers of Woolwich, now the Telecommunications Division of Associated Electrical Industries, Ltd. Here he took an active part in furthering electronic applications to the telephone and, for a number of years, was chief engineer of the Advanced Development Laboratories

engaged on this work. During this time he played a leading part, together with other manufacturers and the British Post Office, first in the establishment of the first electronic automatic exchange at Highgate operating on the time-division multiplex principle, and latterly in the establishment of the first large electronic exchange in Britain in which reed relay speech circuits are controlled by electronic logic circuitry. In recent years he has also been engaged in electronic applications to other forms of telephone switching, in data transmission studies, and methods of achieving economy of speech-band paths over linked transmission circuits. He is now extending his activities to the wider basis of the academic life, where his experiences, especially those of industrial research laboratories, should prove of great value in university research activities with which he will now become associated. He was recently granted a D.Sc. (Eng.) by the University of London for his publications in the fields of electronics and telecommunications, and his new career at the Birmingham College of Advanced Technology will be watched with interest by all who were associated with him in his early activities.

### Nuclear Power Stations

In a statement in the House of Commons on May 25, the Minister of Power, Mr. F. Lee, said that the Central Electricity Generating Board, in inviting tenders for the second nuclear power station to be built at Dungeness, had stated that besides tenders for an advanced gas-cooled reactor station of the kind developed by the Atomic Energy Authority, it was also ready to consider tenders from British industry for water-moderated reactor systems of proved designs such as those developed in the United States. The tenders, which included proposals for both these types, had now been assessed by the Generating Board in conjunction with the Atomic Energy Authority; the advanced gas-cooled reactor showed clear economic and technical advantages over the alternative systems, and had a good potential for further development. It would also generate base-load power more cheaply than a contemporary coal-fired station. Mr. Lee said he had accepted the joint recommendation that an advanced gas-cooled reactor should be adopted at Dungeness, and later added that the advantage would be at least 10 per cent. A corresponding statement was made the same afternoon in the House of Lords, when the advanced gas-cooled reactor was described as a remarkable technical break-through, and Lord Numburnholme asked if some scheme for converting sea-water into fresh water could be incorporated in the contract.

### Expenditure on Overseas Development

In reply to a question in the House of Commons on June 1 as to the aid given by the Ministry of Overseas Development in agriculture, education and technology, Mr. A. E. Oram, Parliamentary Under-Secretary to the Ministry, said that in agriculture estimated expenditure on aid in 1964 was £1·885 million, excluding the cost of the Anti-Locust Research Centre (£140,000) and Desert Locust Control (£12,000), besides new commitments for grants (£3·8 million) and loans (£4·5 million). In addition, expenditure of £12·6 million was incurred in respect of earlier commitments. There were some 180 unfilled vacancies for technical assistance, but 1,342 Overseas Service Aid Scheme posts were filled in 1964 and 61 technical assistance posts. The demand was concentrated largely in East and Central Africa. In addition, under the National Agricultural Advisory Service and the Department of Agriculture for Scotland, 30 posts were created to enable experienced officers to be seconded overseas, and under a studentship scheme 20 British graduates were being trained for overseas service in agriculture. Britain's direct expenditure on education and training overseas in 1964-65, including Common-

wealth Education Co-operation, was more than £16·5 million, about £12·5 million being in the Commonwealth; there were also substantial contributions to international agencies such as the United Nations Educational, Scientific and Cultural Organization, the Expanded Programme of Technical Assistance, and the Special Fund. There were more than 42,000 Commonwealth students in Britain, and expenditure on training in the United Kingdom of students for developing Commonwealth countries, other than under Commonwealth Educational Co-operation arrangements, was estimated at £1·7 million. For 1964-65 estimated expenditure on British teachers overseas under the Overseas Services Aid Scheme was estimated at £1·6 million. Estimated expenditure on aid to technology in 1964 was £4·05 million, including expenditure by the British Council. New commitments for grants totalled £451,000 and for loans £6·86 million, while further expenditure of £18 million was incurred in respect of earlier commitments. It is expected that the whole of the new commitments in all the fields will require some years to disburse.

### Reports of the Estimates Committee

Two recent Special Reports from the Estimates Committee have attracted little attention although they bear closely on the efficiency of Parliament, particularly on its ability to criticize the Executive effectively. Of these, the Fifth Special Report for the Session 1964-65 (Pp. 4. London: H.M.S.O., 1965. 6d.) deals with temporary technical or scientific assistance for sub-committees of the Estimates Committee, which works through such sub-committees. For its evidence, it depends largely on senior officers of Government departments who are experts in the subject under examination, although informed and responsible persons from outside the Civil Service are also consulted. The Estimates Committee has reviewed the present system under which it examines the Estimates with the view of deciding whether its existing powers are sufficient. It considers that on occasion it might be valuable for it to engage the services of someone with scientific or technical knowledge on an *ad hoc* basis for the purpose of a particular enquiry, either to supply information which was not readily available or to elucidate matters of complexity within the Committee's order of reference. Such a person would attend meetings of the Sub-Committee conducting the enquiry when invited to do so, but without power to vote or to examine witnesses. There are two precedents for this procedure. When, in 1921, a Select Sub-Committee was set up to enquire into the organization and administration of the telephone service, the Committee was empowered to appoint from outside its own body such persons as it thought fit to obtain special expert or scientific information, or to advise on the subject-matter of its enquiry. Likewise in 1944, the Select Committee on House of Commons (Rebuilding) was empowered to invite any specially qualified persons it might select to attend any of its meetings in an advisory capacity. The Estimates Committee now recommends that as an experiment the House should pass an order, granting it a similar power limited to the two purposes indicated and on the understanding that anyone appointed will function in the way described. The sixth Special Report for the session (Pp. 4. London: H.M.S.O., 1965. 6d.) deals with sittings of sub-committees overseas. The Estimates Committee and its sub-committees are at present limited to sittings within the United Kingdom. When in the last two sessions members of one of the Sub-Committees were investigating military expenditure overseas they were only able to travel abroad to do so by courtesy of the Minister of Defence, who issued invitations to them and bore the expense on his Vote. Even so, they were not able to sit as a sub-committee to take evidence. The Estimates Committee does not think that it is satisfactory

that it should be dependent on invitations from departments which it may wish to investigate, and it accordingly recommends that its sub-committees should be able, with the agreement of the Committee and by leave of the House, to hold sittings in any overseas territory with the consent of that territory.

### The Australian Academy of Science

THE report of the Council of the Australian Academy of Science for the year ended March 31, 1965 (Pp. 14. Canberra: Australian Academy of Science, 1965), reiterates its concern at the absence of Government replies to the various proposals submitted to it since 1962, covering the establishment of a research museum of Australian biology and compilation of a Flora of Australia, the provision of rockets to enable Australian space research to be developed, and the establishment of a National Science Fund for supporting, on an individual basis, high-quality projects for scientific research. Such apparent discourtesy must be far more frustrating and disheartening to Australian scientists than the reasoned rejection of proposals. During the year the senior fellowship scheme was established on a continuing basis, and the Council accepted responsibility for preparing a new secondary-school text-book on biology for use in Australian schools. Publication of the *Australian Journal of Applied Science* was stopped, but the number of papers published in Australian journals of scientific research increased by 67 during 1964.

### The Smithsonian Institution

THE report of the Smithsonian Institution for the year ended June 1964 is a massive publication of nearly 300 pages (Pp. xiii + 293 + 14 plates. Smithsonian Publication 4595. Washington, D.C.: Government Printing Office, 1965). It expresses the hope that in its wider usefulness the Institution may be able to broaden the traditional co-operation with museums throughout the world. Museums and their related laboratories are entering a new era and their resources are being drawn on as never before for general education, since more than 90 per cent are involved, ranging from simple school-extension programmes to postgraduate fellowships. For these reasons, it is felt that the Smithsonian, with its superb resources, has a great opportunity to serve the museum world in the role of leadership and co-operation. Research on wild populations and undisturbed conditions in Nature is now a matter of urgency. A related objective is to strengthen the position, within science as a whole, of those fields of biology which have the entire organism as their object: ecology, genetics, systematics, botany, zoology, oceanography, microbiology and palaeontology as well as the sciences of man which have for so long been central concerns of the Smithsonian. The Institution has also been active in the international field, and has made a determined effort to carry its activities beyond traditional expeditions and research to co-operation with other Government agencies and private institutions in the development of exchange of persons and exhibition programmes.

### The Zoological Society of London

THE annual report of the Zoological Society of London for 1964 reviews all the activities of the Society during the year. There were 1,816,000 visitors to Regent's Park, a figure only marginally below the seven-year average, and 38,000 more than in 1963. The total number of visitors to Whipsnade Park was 675,000, which, though an improvement on 1963 (616,000), was still well behind the 757,000 visitors in 1961. 39,000 cars were brought into the Park by visitors, compared with some 33,600 in 1963. A particularly important acquisition by the Society during the year was a pair of European bison, presented to the British Forestry Commission by the Polish Forestry Commission and deposited in the Col-

lection. Since February 1963 there has been only a single male of this species in the London Zoo, but it is now hoped to be able to breed this extremely rare animal. Among the more interesting additions to the mammal collection have been a binturong, a Siberian weasel, two hog badgers, two giant pangolins and two spectacled bears. The outstanding exhibit in the aquarium still continues to be the *Arapaima* (*Arapaima gigas*) from South America, which is now almost 5 ft. long—more than three times its length on arrival in June 1962. A new nocturnal section housing pottos, douroucoulis, lemurs, flying squirrels and bushbabies was opened in the Children's Zoo at Regent's Park in the early summer, and has proved a most successful exhibit.

### Desert Locust Control Organization for Eastern Africa

THE first annual report of the Desert Locust Control Organization for Eastern Africa, which covers the period October, 1962–June 30, 1963, is of particular interest (Pp. 32 + map. Nairobi: Government Printer, 1964. 2s.). It records cogently and concisely the stages by which the former Desert Locust Survey developed from an organization financed entirely by Kenya, Tanganyika, Uganda and the British Government, but operating almost exclusively in Ethiopia and Somalia, into a fully constituted international organization of which Ethiopia and Somalia are members. This marks the culmination of the efforts that have been made for a number of years to foster international co-operation in locust control in Eastern Africa. During the period of the report desert locust activity was at a minimum throughout almost its entire area, and the Organization itself was not required to undertake control measures. Some control was carried out by national locust organizations in Somalia and Ethiopia assisted by the United States Regional Insect Control Project. The control potential of the Organization itself was used to conduct surveys which, with the co-operation of the countries concerned, were extended to the Sudan and Arabian Peninsula. The report contains a useful record of such locust activity as occurred, and an account of the research which the Organization is conducting or planning. This research includes locust population dynamics, use of radar in quantitative survey, morphometric studies, aircraft spray equipment and operational methods. The outcome of these projects will be of importance to all concerned with locust control, and future reports by the Desert Locust Control Organization for Eastern Africa will be awaited with interest.

### The London School of Hygiene and Tropical Medicine

THE report on the work of the London School of Hygiene and Tropical Medicine for the year 1963–64 (Pp. 127. London: London School of Hygiene and Tropical Medicine, 1965) outlines the progress made with the modernization and expansion of the School, following the Wolfson Foundation benefaction of £800,000. It is supplemented by reports from the Departments of Bacteriology and Immunology, Biochemistry, Clinical Tropical Medicine, Entomology, Human Nutrition, Medical Statistics and Epidemiology, Occupational Health and Applied Physiology, Parasitology and Public Health, and from the Ross Institute of Tropical Hygiene and the Medical Research Council Environmental Physiology Research Unit. A list of publications during the year is appended.

### The National Institute of Child Health and Human Development

THE Public Information Office of this Institute, which is part of the U.S. Public Health Service, plans to distribute on request every 2½–3 months a news service to workers in this field, which will give information about the Institute's activities and progress. The *News Letter* dated February 1965 contains information about the higher values of the

3 enzymes acid phosphatase, galactose-1-phosphate uridyl transferase and glucose-6-phosphate dehydrogenase found in mongoloid individuals, and also about Public Health Service research grants, and work on the diagnosis and study of retardation done by a new unit in the Institute. There is also a report of a discussion on saving life before birth and items on 'fetology', the name given to the study and treatment of the human foetus *in utero*, and on grants for the study of adult development and ageing.

#### 'Miche' Stains and Reagents for Biology

BUILDING extensions to the premises of Edward Gurr, Ltd., at East Sheen, London, S.W.14, have now been completed at a cost of £25,000 with the view of streamlining operations, more particularly in connexion with the firm's exports expansion programme. This is the second extension since Edward Gurr acquired the original premises in November 1950. The first was built in 1952 (*Nature*, 169, 483, 1952), when the Mayor of Barnes laid the foundation stone of a new laboratory block. The ceremony was performed in the presence of officials of the Board of Trade (Export Promotion Department), Central Office of Information, the British Broadcasting Corporation and the Press. The Company was founded shortly after the Second World War by Edward Gurr, an organic chemist and biologist, primarily to supply the export markets which had formerly drawn on German manufacturers for their needs of biological stains. Another object of the founder was to gain freedom and facilities for research and writing in his own style on the topics closest to him, namely the chemistry and use of biological stains and the simplification and rationalization of histological staining. He has published several books and has contributed a number of research papers to various journals, all with this object in view.

#### Introductory Courses in Genetics

THE fourth edition of Dr. Charlotte Auerbach's *Notes for Introductory Courses in Genetics* (Pp. 42. London: Oliver and Boyd, Ltd., 1965. 8s. 6d.) again emphasizes that the booklet is not intended to compete with any textbook, however elementary. Even less is it meant to be a popular introduction to genetics, although it may prove useful to scientists in other fields who require a concise exposition of the basic concepts and laws of genetics. The object of the book is to help students who attend courses in elementary genetics, especially the short courses given to medical students and first-year agricultural students, and for their special requirements two appendixes have been added. The *Notes* should relieve the students of the necessity of taking their own notes on a subject which requires great accuracy and clarity of terminology. The book has, in fact, grown out of dictations to students, and has successfully replaced these dictations in Dr. Auerbach's own introductory courses.

#### Translation and Interpretation

THE chief features in *The Incorporated Linguist*, the journal of the Institute of Linguists for April 1965, are Mr. S. Soubbotnik's article on "Interpretation in the United Nations and its Specialized Agencies"; Mr. R. Hartman's comparative review of the bilingual dictionaries of English and German; and Dr. van Abeé's discussion of overcoming initial difficulties in teaching a modern language.

#### Psychological Investigation of Card Punching

BEHIND each brief summary of multifarious fact provided by data-processing lie not only the achievements of electronic engineering but hours of humdrum card punching by young women, some of whose supervisors report that for this work the level of intellectual attainment represented by General Certificate of Education (Ordinary Level) passes is a positive drawback. Yet

their work demands manipulative speed and accuracy, with considerable mental alertness in ordering and coding the raw data, and they need 3-6 months training. The National Institute of Industrial Psychology has made a preliminary survey of the problems of selection, training and methods of work that this entails (National Institute of Industrial Psychology. Report No. 18: *Card Punching: a Study of the Work and the Factors that Affect It*. By Leonora Johnston. Pp. 40. London: National Institute of Industrial Psychology, 1965. 8s. 6d.). That problems really exist is indicated by the high leaving-rate among operators, and the standard view that it results mainly from marriage and pregnancy is shown to be untenable. Any programme of selection and training in this field has to face unexpected difficulty in assessing performance, largely because of wide variations in the nature and layout of the information to be punched. The Institute's investigator met the familiar industrial situation of rather elaborate record keeping which everyone concerned knows to be misleading, and although she tactfully accepts the view that it serves well enough for practical purposes it will obviously not meet scientific needs. The report, however, begins to bring the problem within range of systematic investigation, and it is to be hoped that further work can be undertaken in an area where widely differing practices prevail, each at present supported with more conviction than evidence.

#### North Staffordshire Field Club

THE North Staffordshire Field Club celebrated its centenary on April 18. Founded for the purpose of studying the natural history of the district, its scope was soon extended to include local history and archaeology, and early members contributed notably to the knowledge of the North Staffordshire Coalfield. In recent years a close liaison has developed between the Club and the University of Keele; in 1960 the *Transactions of the North Staffordshire Field Club* were incorporated in the *North Staffordshire Journal of Field Studies*, which is edited in the University. The president of the Club for the centenary year is Mr. H. V. Thompson, formerly head of the Department of Chemistry in the North Staffordshire College of Technology.

#### Fossil Tapirs

IN contrast to the voluminous writings on other fossil perissodactyls, tapiroids have been long neglected. Prof. Radinsky's recent monograph, entitled *Early Tertiary Tapiroidea of Asia*, does much to redeem this—a work all the more remarkable when one realizes that the material which is described has lain in the American Museum for more than forty years (*Bulletin of the American Museum of Natural History*. 129, Article 2. By Leonard B. Radinsky. Pp. 181-264+plates 1-4. New York: American Museum of Natural History, 1965. 3 dollars). Radinsky's earlier works have clarified the location of Mongolian Tertiary sites and their stratigraphy. This work sheds new light on the earliest ceratomorphs, a taxum which bristles with taxonomic difficulties. Radinsky describes three new tapiroid genera and rearranges the classification of early tapirs in the light of all known material, mostly Russian and Chinese. His re-grouping of genera within families still leaves an uncomfortably large number of *incertae sedis* specimens. In spite of this, his descriptions of dentitions and limb bones, adequately illustrated, make a welcome contribution. Prof. Radinsky comments on the interesting contrast between the diverse tapiroid fauna of the Asiatic Eocene with the relative paucity of artiodactyls, and the reverse position in contemporary North America and Europe where artiodactyls predominated; he suggests the influence of ecological factors. The 'grande coupure' still remains between early and late Tertiary tapiroids, as it does for numerous other mammalian taxa.

### Pyrenean Prehistory

THE late M. and Mme. St. Just Péquart were well known before the Second World War as amateur prehistorians. They were at the village of Mas d'Aixil during the German occupation and worked on the new gallery found in 1937, completing their investigations four years later. Mas d'Aixil is in the Pyrenees; a river plunges down a valley and turns into the mountain-side, emerging just above the village. The tunnel is large enough to accommodate both the river and a road. Half-way through, to one side, there are extensive caves—so extensive indeed that it is said that during the Albigensian Wars an army took refuge in them and was not discovered. Prehistoric man used some of the galleries, and Stone Age industries have been unearthed from them. M. and Mme. St. Just Péquart had the luck to find a new gallery full of implements and fauna, some of it Aurignacian, but mostly Magdalenian in date, and including some remarkable examples of prehistoric art. The exact location of the gallery is described in the *Annales de Paléontologie* (48-49, now published in one volume), and an account is given of the section obtained; these are followed by a description of the finds—both stone and bone. The implements are very numerous and well fashioned. A number of small engraved rondels occur, as well as pieces of bone sculptured into the form of animals' heads. A few pieces of modelled clay were also found as well as a small, somewhat crude sculpture in bone of a screech owl. Many of the flat pieces of bone carry engravings of animals. But the really remarkable object is a spear thrower, the end of which is carved with a figure of a fawn looking back over its shoulder towards its tail where the head of a bird is incorporated. Very few prehistoric drawings or sculptures show an animal turning its head over its shoulder. The engraved reindeer from Langerie Basée is an example, but the new find from Mas d'Aixil is especially well executed. Many other finds of interest are described, but enough has been said to make it obvious that the *Annales* in which the account of the new finds appears should not be missed by prehistorians.

### Geological Maps of Sweden

THE first of a new series of geological maps of Sweden, combining solid and drift geology on the scale 1:50,000, covers the north-eastern environs of Stockholm (*Geologiska Kartblad*, Serie Ae No. 1, Stockholm NO; with explanatory memoir. Pp. 148. Stockholm: Sveriges Geologiska Undersökning, 1964. Map, 20 kr.; memoir, 5 kr.). In view of criticisms in several countries that the publications of the national geological surveys are becoming increasingly unintelligible to the intelligent layman, this map and pocket-size memoir merit recognition not only as an outstanding piece of geological cartography, but also as a praiseworthy attempt to present a description of the geology in a comprehensive and yet readily comprehensible form. The memoir, which carries a coloured petrological map on the scale 1:100,000, is in Swedish, save for a seven-page English summary; both maps and all illustrations have bilingual legends. In addition to the geological features, the location of ancient monuments is shown on the map and listed in the text. Stockholm now joins the relatively few capital cities—Oslo, Edinburgh and Paris are among the others—where the geological tourist is well catered for.

### The Macaulay Institute for Soil Research

THE latest bound collection of scientific papers from the Macaulay Institute for Soil Research, published during the period 1961-63, has been issued (7. Pp. 24+papers 1-74. Edited by Alexa M. B. Geddes and Rosaleen Noble. Craigiebukler, Aberdeen: The Macaulay Institute for Soil Research, 1964). The titles of 74 papers are listed in chronological order and there is an author index. The work, from seven major departments, naturally

covers a wide range of topics embracing both fundamental research and the application of scientific discoveries to agricultural practice, but an idea of the scope of the publications may be gathered from the following extracts from the titles. Soil formation, the principles of the classification of soils, the genetic soil groups of Scotland; sensitivity in differential thermal analysis, various aspects of clay minerals; microbiology of rocks and weathered stones; the rate of growth of peat and its use in horticulture; the fungal metabolism of compounds related to lignin, the release of ions from minerals by fungal activity; the fractionation of organic phosphate; soil fertility, evaluation of phosphate status, effects of fertilizers on plant production; placement of radioisotopes in the study of root systems; changes in the composition of leaves during growth, aconitase activity in leaves; trace elements in soil, plant and animal.

### Announcements

THE Secretary of State for Education and Science has appointed the Right Hon. Viscount Amory a member of the Medical Research Council as from October 1, in succession to the Right Hon. Lord Shawcross, whose term of membership expires in September. Lord Amory has agreed to be chairman of the Council. He was chairman of the Council during December 1960-July 1961, when he resigned on taking up his appointment as United Kingdom High Commissioner in Canada.

A SYMPOSIUM on "Physiology and Biochemistry of Muscle as a Food" will be held in the University of Wisconsin during July 12-14. Further information can be obtained from E. J. Briskey, Department of Meat Science, University of Wisconsin, Madison.

AN international seminar on "Ekistics and the Future of Human Settlements", organized by the Graduate School of Ekistics, Athens, will be held in Athens during July 20-24. Further information can be obtained from Dr. D. Iatridis, Athens Center of Ekistics, 24 Strat. Syntekmou Street, Athens 136.

AN international symposium on "Swine in Biomedical Research", sponsored by the Atomic Energy Commission and the Pacific North-west Laboratories of the Battelle Memorial Institute, will be held in Richland, Washington, during July 19-21. Further information can be obtained from Dr. L. K. Bustad, Biology Department, Battelle-Northwest, P.O. Box 999, Richland, Washington.

AN international conference on "The Education of Professional Physicists", arranged by the Institute of Physics and the Physical Society under the auspices of the Education Commission of the International Union of Pure and Applied Physics, will be held at the Imperial College of Science and Technology during July 16-21. Further information can be obtained from Miss P. N. Boston, the Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

A SYMPOSIUM on "Thermodynamics, with Emphasis on Nuclear Materials and Atomic Transport in Solids", sponsored by the International Atomic Energy Agency and the Commission on Thermodynamics and Thermochemistry of the International Union of Pure and Applied Chemistry, will be held in Vienna during July 22-27. Further information can be obtained from Dr. O. E. Holley, jun., Division of Research and Laboratories, International Atomic Energy Agency, Kärntnering 11, Vienna I.

ERRATUM. In the communication entitled "Mannosamine in the Cell Wall of *Clostridium welchii* (Type A)", by Dr. B. T. Pickering, which appeared on p. 400 of the April 24, 1965, issue of *Nature*: 1st para., line 10, the words "glutamic acid" should be inserted between "alanine" and "glycine". 2nd para., line 15, the first word should be "galactosamine".

## REORGANIZATION OF THE FORESTRY COMMISSION

IN a written answer in the House of Commons on May 10, the Minister of Land and Natural Resources, Mr. F. Willey, stated that he and the Secretaries of State for Scotland and Wales had comprehensively reviewed the organization of the Forestry Commission, taking account of the recommendations made by the Estimates Committee in its seventh report for the Session 1963-64, with which they found themselves in wide agreement. Among other changes, they had decided that the Commission should be reconstituted with four full-time executive members and only five part-time Commissioners, chosen for their knowledge and experience of commerce, the timber trade, trade union matters, and forestry and the countryside. There will be a part-time chairman as at present, and the staff will be reorganized functionally under the full-time members responsible for forest management, harvesting and marketing, and administration and finance, respectively, and there will be greater delegation to the Conservancies, with headquarters staff in Scotland and Wales. Mr. Willey added that the chairman of the Commission, Lord Waldegrave, was in full agreement with their proposals, and to facilitate the reorganization he and the other Commissioners had placed their offices at the Government's disposal.

These proposals and the other Government observations on the Committee's proposals are set forth in the eighth Special Report from the Estimates Committee\*. Responsibility for forestry has been transferred to the Minister for Land and Natural Resources and the Secretary of State for Wales, who will seek advice from their senior officers, as well as from the Forestry Commission on the broader aspects of forestry. The Forestry Ministers have discussed with representatives of the private woodland owners, and of the timber trade, arrangements to make themselves accessible to a direct formal approach. It is confirmed that the Commissions should continue to be responsible for promoting the interests of private as well as of State forestry, and the production and supply of timber. However, it is suggested that development of the position of the Home Grown Timber Advisory Committee would ease the dilemma of the private woodland owners and the timber trade. They accept that the administrative staff in the Commission's headquarters, and particularly the Commissioner in charge of administration and finance, should play a full part in determining

policy, and it is recognized that the higher posts should not be limited to any one class or profession. It is believed that the new functional organization will provide improved prospects of promotion for the executive class. A system of valuation for the Commission's forests, which is under discussion with the Treasury and the Comptroller and Auditor-General, will be introduced experimentally for the next two or three years. The recommendations that a brief explanation of the most significant items of income and expenditure should accompany the summary of the financial results in future annual reports, and that the Commission should establish a new Costings Branch, are also accepted.

On the recommended study of the present procedures for acquiring land for forestry purposes, the Ministers express the opinion that close consultation with the agricultural departments is essential concerning the change of use from farming to forestry, which is inherent in the forestry programme. They are satisfied that adequate machinery exists for resolving speedily, if necessary at Ministerial level, any conflict that may arise. In England the Forestry Commission is already undertaking a pilot survey of agricultural and forestry land use with the Ministry of Agriculture, Fisheries and Food in Northumberland and Cumberland, and possibilities of similar surveys in Wales are being explored. The Ministers also agree that Parliament and the public should be informed both of the planting programme to which the Government is working and of the considerations on which it has been formulated. However, they decline to commit themselves as to the frequency with which it would be appropriate to review the programme, or the means to be used to furnish information to Parliament. The position of marketing within the Commission will be strengthened by the appointment of a Commissioner as full-time head of harvesting and marketing, and a new branch has already been added to the Marketing Section. The Commission is also discussing with the Civil Service Union a revised grading structure and scales of pay for the forester class which, it is hoped, will significantly reduce the wastage of trained foresters. In the reorganized Commission it is proposed to amalgamate the Education and Training Branches, vesting responsibility for them in the Commissioner for Administration and Finance. In consultation with other Departments, the Forestry Commission is reviewing the procedure for making Tree Preservation Orders, and the Forestry Committee of Great Britain and other interests concerned will be consulted at the appropriate time.

## THE AUSTRALIAN DEFENCE STANDARDS LABORATORIES

THE Australian Defence Standards Laboratories with their establishments at Maribyrnong (Victoria), Alexandria (New South Wales) and Finsbury (South Australia) provide a scientific service for all branches of the Defence Service, Civil Defence and the Department of Supply. The Laboratories deal with problems which arise in the provision and use of defence material, within the fields of chemistry, physics, metallurgy and engineering.

On July 18, 1963, 'Operation Blowdown' was successfully carried out at Iron Range in North Queensland, and a reproduction in colour of the fireball produced by the trinitrotoluene explosion forms the striking cover illustration of the annual report of the Laboratories for the year ended June 30, 1964\*. As predicted, the blast of the

explosion produced extensive damage to the forest. Trees were uprooted and broken and there was a substantial pile-up of debris far from the seat of the explosion. A high order of spherical detonation was achieved, but the Mach stem of the explosion was severely distorted by the forest, an effect previously unknown. Army personnel stationed within the area of the operation assessed the tactical implications of the debris and the displacement hazards to troops were determined by articulated dummies placed at appropriate positions. Other scientific data of value were collected by instruments, some of novel design, placed on trees within the forest. The combined results provide a sound basis for the assessment of nuclear weapons effects in a tropical forest area.

In the Chemistry Division work has continued on the application of mass spectrometry in the structural analysis of organic compounds and a grating infra-red spectrophotometer has been used to obtain high-resolution

\* Commonwealth of Australia. Department of Supply. Annual Report of the Defence Standards Laboratories, 1963-64. Pp. 50. (Ascot Vale, Victoria: Defence Standards Laboratories, 1964.)

vibration-rotation spectra of small molecules containing phosphorus. A rapid and accurate photometric method, based on the reduction of dichromate, was developed for the determination of the excess of zinc in zinc oxide. Zinc oxide is of interest as a photoconductor in electro-photographic processes. Measurements were made with a low-frequency torsion pendulum of the dynamic modulus and internal friction of irradiated samples of polytetrafluoroethylene at temperatures between  $-180^{\circ}\text{C}$  and  $150^{\circ}\text{C}$  in order to obtain new information about the effects of  $\gamma$ -radiation. The results indicate that irradiation under high-vacuum conditions produces some random chain scission, but cross-linking also occurs and together with an unusual increase in crystallinity the polymer becomes more rigid and brittle.

The Metallurgy Division was mainly concerned with the investigation of chromium alloys with the object of developing strong high-temperature alloys. Metallographic investigations of the surface-damaged layer on abraded surfaces of germanium previously reported on have been extended to other semiconductors, in particular silicon and indium antimonide. It has been established that an extensive arrangement of cleavage cracks, each associated with an array of dislocations, is a common feature. In indium antimonide, the damaged layer also contained glide dislocations and twins. The general mechanism for abrasion seems to be that a system of cracks develops about the indentation made by the contacting abrasive particles, a fragment of the surface being removed whenever a number of the cracks intersect appropriately. Tests made on single crystals of germanium, polished and then etched with *OP-4*, showed that Griffith cracks did not appear until after the test pieces were stressed. Once the cracks formed they become preferred sites for the nucleation of dislocations and when

the cracks reached the critical Griffith size brittle fracture of the material occurred.

A new group was set up in the Physics Division to carry out research, under the supervision of Dr. P. W. A. Bowe, on the physics of lasers. The spatial and spectral coherence of a small ruby laser is being investigated. Pumping efficiency using a high-power Q-switch device is also being investigated and a Pockel-cell light switch with a rise time of less than 10 ns has been developed. A long-term programme of research on laser materials with initial emphasis on organic complexes has been initiated. In metrology, a screw-pitch measuring interferometer has been used to measure pitch over a 2-in. length to an accuracy of  $\pm 6 \times 10^{-4}$  in.; new techniques for flatness measurement and for the measurement of large jigs and components have been developed; and the accuracy of the frequency standard has been improved by the installation of a quartz crystal oscillator of the Warner type and a phase tracking receiver, for comparison with standard very low frequency transmissions.

Various other investigations and devices described in the annual report include a probe to detect the passage of a pressure front; photoelectric fuse-timing equipment; a rapid action dilatometer, based on the type used at the British Welding Research Association, to obtain continuous cooling transformation diagrams of low-alloy steels using heating and cooling rates appropriate to welded joints; the welding of thin-wall titanium tube; the tearing of textiles; the varnish-holding properties of timbers; and the detection and determination of toxic gases. The report concludes with a list of the various personnel and their status, the publications of, and lectures given by, members of the staff of the Laboratories and the names of the Governmental and other committees on which the establishment is represented. S. WEINTROUB

## TEXAS INSTRUMENTS, INC.

AT the annual meeting of Texas Instruments, Inc., on April 22, in Dallas, the president, Mr. P. E. Haggerty, reported on the activities of the company during 1964 and explained the principles and system of management. He mentioned that key personnel were deliberately and consistently moved from one job category to another and upward from one level of management to the next. During the nineteen years since the Second World War the company had grown to more than 150 times its original size, but it had not been necessary to go outside the company in order to fill any principal managerial position. The demand for highly trained personnel with advanced degrees continues, and if the growth rate of degree personnel—both first degree and higher degree—of 1960-64 is maintained, Texas Instruments will require some 12,000 college-trained personnel by 1974, including about 750 of Ph.D. status.

New record levels in both sales and products were achieved during 1964. Net sales, which totalled some 327.5 million dollars, were up by 18 per cent, and approximately one-fifth of the sales were from operations conducted outside the United States. The organization for the distribution of industrial supplies expanded its activities into international markets by the establishment of branches in Stuttgart, Germany, and in London. Branches in the United States are in Dallas, Houston, Kansas City, Tulsa and Boston.

Most of the company's products stem from investigations of materials at the fundamental structure-of-matter level, and a great variety of metals and non-metallic elements, including semiconductor materials, are refined and processed before fabrication into electrical or electronic components, or assembly into electronic systems. Zinc-clad aluminium for rotary-press printing plates, and copper-clad materials with performance characteristics

equal to or superior to those of solid copper, were two new developments during 1964. Semiconductor-grade silicon, and silicon-carbide clad parts, were in increased demand, and the company continued to be the main supplier to the U.S. Navy of fabricated nuclear fuel.

More than 200 new semiconductor and electronic component products were introduced during the year. Transistors for television receivers, and plastic-packaged silicon transistors for low-cost applications, were in growing demand for the industrial and domestic market. New components for the space and defence industries included an advanced series of silicon planar-epitaxial power transistors, a unique glass silicon rectifier with very high-voltage capability, and super-sensitive silicon-controlled rectifiers of reduced size and weight.

The semiconductor integrated circuit was first introduced in the Texas Instruments Laboratories during 1958, and now 86 standard circuit types are manufactured. A recent order for integrated circuits by North American Avionics Autonetics Division amounts to 11 million dollars. The circuits are to be used for the guidance and control system of the U.S. Air Force *Minuteman II* intercontinental ballistic missile. Texas Instruments semiconductor plant at Bedford, England, began the production of monolithic circuits during 1964 and the integrated circuits have been designed for the European six-nation space exploration effort called ELDO-ESRO\*, for a new hearing aid, and for several industrial programmes.

During 1962, Texas Instruments introduced, on a limited scale, a completely new approach to seismic exploration. It consists of the application of statistical communications theory to seismic data processing, and

\* European Launcher Development Organisation—European Space Research Organisation.

utilizes specially developed field techniques and signal-intensifying processes. The method has since been fully demonstrated and evaluated, and in many of the more difficult exploration areas of the United States and Canada it has proved to be an advanced tool for petroleum exploration. Advanced digital seismic data-processing centres have been established in New Orleans, Louisiana, and Midland, Texas, to augment the Dallas centre and to meet increased demands. A fourth centre began operation during January 1965 in Calgary, Alberta, and a fifth is to be opened shortly in London, England. A seismic detection system for perimeter defence in jungle warfare has been

delivered to the U.S. Marine Corps, and a scheme for geophysical experiments to be carried out on the surface of the Moon under the *Apollo* programme has been prepared. Mr. E. McDermott, who was co-developer of the seismic reflexion technology which has been applied universally in exploration for petroleum and other mineral deposits, and who was co-founder in 1930 of Texas Instruments' predecessor company, Geophysical Service, retired as chairman of the executive committee of Texas Instruments, Inc., on December 31, 1964, and Mr. Haggerty, president and chief executive officer, has assumed also the office vacated by Mr. McDermott.

## THIN FILM RESEARCH

THE twelfth meeting of the Thin Films Group (formerly the Dielectrics Evaporation Group) was held at Harlow during March 24-25. The Research Laboratories of Associated Electrical Industries and Standard Telecommunication Laboratories, Ltd., acted as joint hosts, and visits were made to both of these. The following papers were read: "Ellipsometry", by Mr. B. H. Clausen (Standard Telecommunication Laboratories, Ltd., Harlow); "Defects in Evaporated Silicon Films", by Mr. D. J. Thomas (Standard Telecommunication Laboratories, Ltd., Harlow); "Nucleation Studies on Freshly Cleaved Crystalline Surfaces", by Mr. D. Stirland (Alan Clark Research Centre, Caswell); "Nucleation and Charge on Glass Substrates", by Dr. R. Hill (Electrical Research Association, Leatherhead); "Lorentz Electron Microscopy: Magnetic Imaging in the Electron Microscope", by Mr. A. Green (International Computers and Tabulators, Stevenage); "Oxidation in a Glow Discharge to Prepare Dielectric Films", by Mr. D. White (Associated Electrical Industries, Research Laboratories, Harlow); "Conduction Processes in Dielectric Films", by Mr. J. Simmons (Standard Telecommunication Laboratories, Ltd., Harlow); "Some Readily Evaporated Semiconducting Compounds", by Dr. J. Zemel (Imperial College of Science and Technology—read by Mr. Juhasz, also of Imperial College); "Initial Stresses in Evaporated Films", by Mr. P. Carpenter (Alan Clark Research Centre, Caswell) and Mr. J. D. Wilcock (Imperial College of Science and Technology).

The theme of this meeting was the study of surfaces with special reference to the early stages of growth in thin films. Perhaps the most interesting new results presented were those of Stirland and Hill, whose papers were to a large extent complementary. In the hope of finding a reproducible surface, which is the dream of every electron microscopist, Stirland has cleaved single rock salt crystals *in vacuo* and evaporated gold from the same source on to the two faces produced. Topographically, one should be a mirror image of the other apart from damage produced in cleaving. He has used a combination of optical microscopy and numbered specimen grids to locate the equivalent areas on the two faces for electron microscopy. Results showed excellent correspondence of cleavage step and dislocation decoration, but no exact correlation of nucleation site position along the cleavage steps or on the flat areas in between. Exposure of one of the crystal faces to moist air before deposition showed considerable effects on the decoration pattern produced.

Hill has examined the effects on film structure both of electrons incident from the source and of the application of a d.c. field across the growing film. His micrographs show that both processes can affect the type of nucleation and growth and the number of nucleation sites available. His work was done with gold on glass substrates at pressures of  $10^{-4}$  mm mercury or better. The use of Hill's technique to prevent stray electrons from the source striking the substrate might perhaps affect some of

Stirland's results on nucleation site correspondence. In order to detect the presence of surface charges on the substrate prior to deposition, a potential probe was applied. This gave, in fact, a very sensitive indication of the beginning of nucleation.

The paper on ellipsometry described a technique which is somewhat unfamiliar to many. Using a collimated beam of elliptically polarized light reflected from the specimen surface, the growth of a thin film can be followed *in situ* by observing changes in the optical constants. The method can be applied to films immersed in liquids and hence is well suited to investigations of anodic film growth and of corrosion or adsorption processes. Owing to the number of variables involved it is necessary to use computer techniques to obtain calculated curves to which the experimental results are fitted as well as possible.

Lorentz electron microscopy is a highly specialized method for examining the magnetic structure of very thin films. A stream of electrons passing near a region of magnetic inhomogeneity is deflected in such a way as to cause an intensity distribution on the screen which corresponds to the variation in the magnetic structure of the film. This method can reveal not only domain walls but also the fine magnetic structure within the domains, and such applications were described in detail by Green.

Electron microscopy has been applied to the study of stacking faults in 'epitaxially' grown silicon deposited by evaporation and by vapour deposition. The incidence of such faults is greatly increased by the presence of silicon carbide formed from pump oils. It is interesting to see that, according to the workers at the Standard Telecommunication Laboratories, Ltd., the use of a gold silicon alloy to promote epitaxy (see Nielson, S., *Nature*, 205, 755; 1965) increases the liability to form faults in the deposit due to thermal strain.

The difficulty of depositing silicon throws into high relief the ease with which single crystal films of lead sulphide, telluride and selenide (and perhaps of related compounds) can be deposited by evaporation. Measurements on the electrical and optical properties of these materials by Zemel, and, in particular, of the electronic mobilities, show that the values obtained approach those of bulk single crystals. (Thus, lead telluride shows a bulk value of 30,000 and a value of 23,000 has been obtained for the film at 77° K.) Juhasz has examined these films by electron diffraction and was able to show an almost perfect Laue diffraction pattern. Since epitaxy was observed even with lattice-misfit greater than 50 per cent it seems that, for these materials at least, substrate surface state is by far more important than lattice correspondence. This was confirmed by Pashley during the ensuing discussion. Juhasz concluded with a graceful compliment to the pioneering work of Wilman, who demonstrated the epitaxy of these compounds as early as 1938.

The relation between details of films structure as revealed by electron microscopy and the mechanical and

electrical properties of the films is an essential link in any comprehensive investigation of film growth. Carpenter and Wilcock (both of whom are working under the direction of Mr. D. Campbell, one in a university, the other in a commercial laboratory) are using very sensitive measuring equipment for the study of initial stresses in thin films of a type on which structural data are available. They are at present seeking to relate the onset of visible nucleation with the first appearance of stress.

White has investigated the preparation of thin insulating films by 'field-assisted anodization' or 'biased sputtering'. Results so far do not fully confirm claims made by some workers in the United States that the process is comparable with aqueous anodization. It appears to differ not only in its low-current efficiency but also in the properties of the films prepared, and the independence of their thickness of applied bias voltage.

J. H. BRUM

## MECHANISM OF CELLULASE ACTION

A ONE-DAY symposium on the mechanism of cellulase action, under the auspices of the Molecular Enzymology Group of the Biochemical Society, was organized by the Shirley Institute on May 28, 1965. Dr. J. Honeyman, who presided, commented that Mr. Selby took this opportunity to arrange a symposium because both Dr. Elwyn T. Reese, from Natick, Massachusetts, and Dr. Bruce A. Stone, from the University of Melbourne, were at present working in the United Kingdom. The Shirley Institute had for several years been active in cellulase research, particularly in work designed to elucidate the mechanism of the biodeterioration of cotton.

K. Selby (Shirley Institute) gave the first paper on the enzymatic degradation of cotton. He stressed that since many 'cellulases' classified by Reese as  $C_6$  can attack soluble cellulose derivatives or swollen cellulose but not native cellulose, the structure of the solid cellulose must govern its susceptibility to attack; if we knew more about the structure we would understand the enzymes better, and vice versa. Although opinion is now tending towards the belief that cotton is entirely composed of crystalline microfibrils without amorphous regions, there exist inhomogeneities in the structure, ranging in size from interfibrillar holes to the layer-structure of the cotton hair, and these may provide sites for enzymatic attack. If cotton could be chemically modified in these accessible regions it might be protected against attack, and this has been done with some success by Mr. Colbran at the Institute by reaction with phenyl isocyanate under non-swelling conditions. Work on the cellulase system of *Myrothecium verrucaria* was reported; exclusion chromatography separated a  $C_6$  from two other components both capable of weakening cotton, and both, like the activity of the crude filtrate, 'exhausted' in the process. The cellulase of *Trichoderma viride* does not suffer from this disability and seems to be a better agent for examining cellulose structure.

In subsequent discussion, J. O. Warwick (Shirley Institute) made it clear that it is still possible to explain the physical and chemical properties of cotton which had previously been attributed to the amorphous part of its structure.

B. A. Stone (University of Melbourne) then gave an account of his work on the purification of the exo- $\beta$ -1,4-glucanase (cellulase) of *Aspergillus niger* and its action on glucans with mixed 1,4- and 1,3-linkages. Elution chromatography removed cellobiase (probably an exo- $\beta$ -1,4-glucanase) and endo- $\beta$ -1,3-glucanase (laminarinase) and the resulting cellulase digested carboxymethylcellulose with a fall in viscosity that demonstrated its chain-cleaving action. Barley glucan was broken down by this cellulase to give some glucose, cellobiose and mixed-link tri- and tetra-saccharides both with 1,4-linkages at the reducing ends. This result confirms that of Perlman and Reese with *Streptomyces* cellulase and should be interpreted in the same way. However, Stone found that the cellulase still contained exo- $\beta$ -1,3-glucanase and that after removing this by adsorption on insoluble laminarin the products of digestion of barley glucan were significantly changed. Glucose was practically absent, but there were present, as stable products, about 20 per cent of penta-

saccharides and higher sugars which, so far as their structures had been determined, all showed the cellobiose grouping at the reducing end. This purified cellulase should be a powerful tool in the investigation of mixed-link glucans.

E. T. Reese (Quartermaster Research and Engineering Center, Natick, Massachusetts) reviewed work on  $\beta$ -glucanases, leaving a vivid impression of the multitude and variety of these enzymes and the complexity of their specificity. In particular, the work of Perlman showed that several endo-glucanases are not specific to the bond being broken but to the nature of the reducing end-unit being liberated. A surprising example of this is that, acting on a glucan with alternate 1,3- and 1,4-linkages, cellulase, producing cellobiose, would attack the 1,3-linkages, and laminarinase, producing laminaribiose, would attack the 1,4-linkages. How far this is true of all endo-glucanases is not clear. The growing class of known exo-glucanases act from the non-reducing end of the glucan; many of them liberate disaccharide molecules, and some have been shown to attack more than one kind of bond. Some exo-glucanases are blocked in their endwise action by substituent groups and branches in the glucan, but a case was given of an exo-1,3-glucanase, from a basidiomycete, which is not stopped by 1,6-branchpoints in a 1,3-glucan.

C. C. Maitland (Shirley Institute) described present work on the cellulase of *Trichoderma viride* and its attack on cotton, which it is able to solubilize entirely. Exclusion chromatography on 'Sephadex' G-75 separates the system into three major components. One component, of low molecular weight, accounts for the greater part of the activity against carboxymethylcellulose but plays no recognizable part in the solubilization of cotton. The two other components are probably identifiable with Reese's  $C_6$  and  $C_1$ , the  $C_6$  having activity against carboxymethylcellulose and cellobiose, while  $C_1$  has little or no such activity but acts synergistically with  $C_6$  in solubilizing cotton. The nature of this synergism, first found by Reese and co-workers but now shown more markedly than before, was discussed. The implied division of labour could be based on the structure of the cotton hair, but this seems unlikely because acid degradation and ballmilling, although destroying the large-scale structure of cotton, do not entirely remove the synergistic effect. It is generally assumed that  $C_1$  initiates the attack on cotton and  $C_6$  follows; this is very likely, but there is no direct evidence for it. However, the small solubilizing power of  $C_1$  acting alone is enhanced when the incubation with cotton takes place on a dialysis membrane; this indicates that an inhibitory product of  $C_1$  action, which  $C_6$  would presumably have removed, is now able to diffuse away.

G. Halliwell (University of Strathclyde) then spoke of his work on cellulases at the Rowett Institute. Rumen bacteria, although capable of extensive breakdown of solid cellulose, do not yield powerfully cellulolytic filtrates, but *Trichoderma* species do both, and the breakdown of fibrous cellulose (cotton) was investigated by using their filtrates. Of particular interest was the observation that an early stage of attack, noticeable by the breakdown of the cotton into insoluble fragments, of which the smallest were capable of passing through a

No. 3 porosity glass sinter, was distinct from the subsequent conversion into reducing sugars. This initial attack was most rapid at a markedly lower pH and might perhaps be caused by a different enzyme.

N. J. King (Forest Products Research Laboratory) described the present state of his work on the cellulase of *Coniophora cerebella*. This is classified as a brown-rot fungus, capable of digesting the polysaccharide of wood and leaving a skeleton structure of lignin. Electron-micrographs showed how this attack was widespread and not confined to the immediate neighbourhood of the fungal hyphae. The widespread nature of the attack was also illustrated by the production, in the early stages of fungal invasion, of more soluble sugars than the fungus can utilize. *Coniophora* has been found to grow easily on cellulose in submerged culture, but cellulase active against compact native cellulose has not yet been obtained. Filtrates contain a cellulase active against swollen cellulose, carboxymethylcellulose, and against cellodextrins,

particularly cellotetraose and higher analogues. This cellulase has been successfully fractionated by elution chromatography on DEAE-cellulose giving three components active against carboxymethylcellulose, which were shown to be distinct by electrophoresis on polyacrylamide gel.

In a general discussion, C. van Bochove (T.N.O., Delft, Netherlands) mentioned his experience of an interesting case of protection of cotton from microbial decay by substitution reaction at the right sites. Methylol-chloroacetamide reacts with cotton and protects it against decay at a degree of substitution of 0.06. If the chlorine is removed by hydrolysis, protection remains; yet the resulting substituent group, applied directly as methylol-glycolamide, gives no protection, presumably because the substitution is not in the right place. J. Dlugosz (Shirley Institute) spoke of the interesting surface features shown by electron-microscopy of cotton attacked by the cellulase of *T. viride*. C. C. MATTLAND

## BINDING OF XENON TO SPERM WHALE MYOGLOBIN

By DR. BENNO P. SCHOENBORN, DR. HERMAN C. WATSON and  
DR. JOHN C. KENDREW, C.B.E., F.R.S.

Medical Research Council Laboratory of Molecular Biology, University Postgraduate Medical School, Cambridge

IN 1946 Lawrence *et al.*<sup>1</sup> and Tobias *et al.*<sup>2</sup> suggested that xenon might be expected to have anaesthetic effects in consequence of its relatively large inducible dipole. In 1951 Cullen and Gross<sup>3</sup> confirmed that xenon was indeed an anaesthetic agent in man<sup>4</sup>. The electron cloud of xenon is, of course, spherically symmetrical, so its narcotic activity cannot depend on any specific structural grouping as had often been supposed<sup>5</sup>, and therefore novel theories of anaesthesia were proposed to explain the action of anaesthetics in general and of xenon in particular<sup>6-8</sup>.

During further investigations of the anaesthetic action and distribution of xenon it became apparent that more xenon is transported by the blood than would be expected from its solubility in the plasma. Solubility experiments then proved that xenon reversibly binds to haemoglobin and myoglobin<sup>9-11</sup>. Since the structures of sperm whale met- and reduced myoglobin have been determined, and nearly all the 1,260 non-hydrogen atoms have been located (J. C. Kendrew and H. C. Watson, to be published), it seemed possible to determine the mode of attachment of xenon to myoglobin without difficulties by the difference Fourier method. Such an X-ray diffraction analysis of crystalline sperm whale myoglobin in equilibrium with xenon has now been carried out. The results prove xenon to be bound to one specific site which is buried in the interior of the molecule and is nearly equidistant from one of the pyrrole rings in the haem group and the ring of the haem-linked histidine. The experimental details and results of the investigation follow.

Sperm whale metmyoglobin, prepared by the method of Parrish and Kendrew<sup>12</sup>, was crystallized from an 80 per cent ammonium sulphate solution at pH 6.8. Crystals were mounted in a special cassette and equilibrated with xenon at 2.5 atm. for 12 h before and during their X-ray exposure. The intensities of the *hk0*, *h0l* and *0kl* reflexions were collected to 2.8 Å resolution on multiple film precession photographs with copper *Kα* radiation from a rotating anode X-ray tube. The exposure times were much longer than usual owing to the strong absorption of the X-rays by the xenon gas in the cassette. The intensities were measured with a semi-automatic microdensitometer; corrected for Lorentz, polarization and temperature factors and then scaled to the native metmyoglobin data.

Difference Fourier projections were calculated using appropriate versions of the general equation:

$$\Delta\rho_{(x,y,z)} = \frac{1}{V} \sum_h \sum_k \sum_l \{ |F_{(x,y,z)}| - |F_g| \} \exp \{ -2\pi i (hx + ky + lz) + i\alpha \}$$

$|F_g|$  and  $|F_{(x,y,z)}|$  represent the moduli of the structure amplitudes of the native myoglobin and its xenon derivative respectively,  $\Delta\rho_{(x,y,z)}$  the difference in electron density between the two compounds. The phase angles used were those for native sperm whale myoglobin, as determined by multiple isomorphous replacement<sup>13</sup>.

The use of a set of only approximate phases in a difference Fourier synthesis results in reduced peak heights for non-centrosymmetric projections. Luzzati<sup>14</sup> showed that the peak height of an atom not included in the phase determination depends on the ratio of the excluded electrons to the included ones. In this case, where the excluded electron density is small, the theoretical expected reduction of peak heights in non-centrosymmetric sections is of the order of 40 per cent and agrees well with the observed results.

Each of the difference electron density maps of the *hk0*, *h0l* and *0kl* projections (Fig. 1) shows only one, nearly circular, peak corresponding to a spherical atom with co-ordinates  $x = 0.177$ ,  $y = 0.864$ ,  $z = 0.168$ . The remaining areas of the maps are relatively featureless, indicating that the degree of isomorphism is high and that xenon atoms are not present at subsidiary sites to any appreciable degree.

The xenon atom is nearly equidistant from the haem-linked histidine and a pyrrole ring of the haem group; it is in contact with all the atoms in both rings. The neighbourhood of this binding site is shown in Fig. 2a and b, and the relevant approach distances are tabulated in Table 1.

The xenon atom in the myoglobin interior lies between a non-polar area and an area which is partially polar, indeed charged. This suggests that this complex is stabilized by charge-induced dipole moments, by dipole-induced dipole moments and by London interactions. In addition, there is an entropy gain due to the transfer of the xenon from the aqueous surface into the interior of the protein. Unfortunately the charge distribution on the

Fig. 1. a, 400 difference electron density map; b, 400 difference electron density map

haem group and the sizes of the various dipoles are still unknown; it is therefore not possible to calculate the degree of polarization and hence the charge-induced dipole and the dipole-induced dipole binding energy of the xenon atom. The entropy gain, which arises from the xenon transfer, could be estimated if the temperature-dependent solubilities of the gas in ammonium sulphate and in a non-polar solvent were known<sup>18</sup>.

Table 1		
Group	Atom	Distance < 5.5 Å
Leucine F4	O (carbonyl)	4.7
	O (carbonyl)	4.6
	Ca	4.9
	Ca	4.4

	OVVR	5.4

The size of the London interaction energy can, however, be calculated from the electronic dispersion interaction between molecules<sup>19</sup>. This interaction is given by

$$W = \sum_j \frac{3}{2} \frac{P_{ss} P_j E_{ss} E_j}{r_{ss,j}^6 (E_{ss} + E_j)}$$

$P$  = polarizabilities,  $E$  = electronic excitation,  $r_{ss,j}$  = distance between xenon and  $j$ th atom. Taking the excitation value for xenon to be 12 eV, the average excitation value for its neighbours to be 13 eV, and the polarizabilities to be 4 Å<sup>3</sup> and 2 Å<sup>3</sup> respectively, we obtain an interaction

Fig. 2a. Location of xenon site in myoglobin

Fig. 2b. Model of structure in the region of the xenon atom. The haem group is to the right almost edge on, and the haem-linked histidine can be seen almost above the xenon atom. The other atoms shown are parts of the main chain of helices F (top left) and H (below)

Fig. 3. Nomenclature of atoms in haem group (Table 1)

energy of about 10.2 kcal. This figure for the total energy is a minimum: in practice it will be increased by the other energy terms which have been mentioned here.

It should be pointed out that this is not a hydrophobic stabilization (hydrophobic stabilization occurs when two or more non-polar groups associate to decrease the interaction with water); there is no indication in the 1.4 Å three-dimensional Fourier synthesis of the native protein, under normal conditions, that a water molecule occupies the xenon site.

## EVIDENCE FOR THE ROLE OF BOUND WATER AND PARTIAL DESICCATION IN CARCINOGENESIS

DR. R. BATHER

Saskatchewan Research Unit of the National Cancer Institute of Canada

AND

PROF. S. J. WEBB and PROF. T. A. CUNNINGHAM

University Hospital, University of Saskatchewan, Saskatoon, Canada

RELATIVE humidity (*RH*), temperature and chemical additives have all been shown to determine the response of a microbial cell to drying in air<sup>1-3</sup>. Experimentation has pointed to structural changes in essential macromolecules resulting from loss of bound water as being responsible for cell death. This bound water can be replaced by certain chemicals during drying which are more stable than water and maintain the structural and functional integrity of the macromolecules<sup>4,5</sup>. Inositol (hexahydroxy cyclohexane) is the best stabilizing agent of many chemicals tested for protective ability against desiccation damage. This is assumed to be due to its structural similarities with water, its symmetry, its non-volatility and its lack of toxicity.

In metabolic experiments many enzyme changes were seen in desiccated cells whether protected with inositol or not. However, inositol did preserve the protein synthesizing ability of dried cells<sup>6,7</sup>, thus suggesting its interaction with ribonucleic acid (RNA). Further evidence for interaction with RNA was obtained when it was shown that Rous sarcoma virus (RSV) could be protected against desiccation death by inositol<sup>7</sup>.

Recently, studies on the effects of ultra-violet light, visible light and X-rays on survival of bacteria and viruses have produced added evidence for the important role of bound water in biological integrity<sup>8-11</sup>. It has become apparent that changes in molecular bound water are involved in radiation damage and can be prevented by inositol in carefully controlled experiments.

Finally, two other phenomena associated with the desiccation of bacteria were deemed important and stimulated further work with animal cells. One was the observation that RNA was released in greater amounts from cells protected with inositol than from unprotected cells. The other was that mutant cells appeared more frequently after desiccation with or without radiation treatment at certain *RH* levels<sup>12,13,14</sup>. When the work was extended to animal cells it became obvious that controlled desiccation in aerosols as employed with bacteria and viruses was not possible with the equipment available, due to mechanical destruction of the cells. However, a variety of cells held in suspension for varying lengths of time were protected against death by inositol<sup>14</sup>. Virus-infected cells released increased amounts of virus in inositol, and drying on Petri dishes in the presence of inositol resulted in increased virus release compared with cells dried from balanced salt solutions (BSS)<sup>15,16</sup>.

Quite independently of the work described here, Falk *et al.*<sup>17</sup> have published data showing that removal of bound water from deoxyribonucleic acid (DNA) results in the loss of structural integrity. This bound water begins to be removed as the *RH* is lowered below 70 per cent and about 5 molecules per nucleotide are removed when the *RH* reaches about 55 per cent. Still further water is removed below this level. A similar situation may exist for RNA and protein molecules, and Klotz<sup>18</sup> has discussed the importance of the hydration sheath as an ice-like lattice in fixing the structure and properties of protein

and nucleoprotein macromolecules. Warner<sup>17</sup>, using the stereochemical properties of inositol, has shown that these compounds can interact with protein layers and probably other biological macromolecules in the same way as water, but afford a much more stable system than water because of the rigidity of the hydroxyl positions in inositols. Thus the idea that bound water is intimately concerned with maintaining the structural, and thereby the functional, integrity of biological macromolecules is becoming increasingly recognized.

To discover whether tumour viruses other than RSV could be released in infectious form by drying the tumour cells an experiment was performed with Ehrlich ascites cells. This tumour is known to carry various murine leukaemia viruses<sup>18-20</sup>. Ehrlich cells were obtained from routinely transplanted Swiss mice, washed once in 5 per cent inositol solution and re-suspended in 5 per cent inositol to give about  $10^7$  cells/ml. 1-ml. aliquots were pipetted on to 60-mm Petri dishes and the cells were allowed to settle for 1 h at 37° C. After decanting the supernatant the cells were dried in a 'Blue M Vapor Temp' humidifier cabinet for 30 min at RH 40 per cent at room temperature. After drying, the cells were gently scraped off the glass into equivalent amounts of 5 per cent inositol solution, and centrifuged. The supernatant was filtered through a 'Millipore' 450-mμ filter to remove all cells and the filtrate was inoculated into 8-week-old female Swiss mice (0.2 ml. intraperitoneally). The cells were washed in 5 per cent inositol, re-suspended and inoculated into a similar group.

Some of those given the filtrate died with acute leukaemia beginning about 5 months after inoculation. At 12 months, when all survivors were killed, the incidence of leukaemia was as shown in Table 1. None of the animals developed ascites tumours, and since only 10 Ehrlich cells are required to produce tumours in 50 per cent of our Swiss mice this must indicate almost complete cell destruction.

However, all but one of the mice given the dried cell filtrate developed leukaemia and about half of those given cellular material did so. Most of the leukaemias were lymphoblastic in type with large thymus tumours as well as lymph node, liver, kidney and spleen involvement. Some of those developing later and discovered at autopsy appeared to be mixed lymphoblastic-lymphocytic neoplasms with cells characteristic of both types. Three of the leukaemias have so far been transplanted by both cells and cell-free filtrate.

The above experiment, along with the results already reported for RSV<sup>13</sup>, shows that some tumour viruses are released in highly infectious form by drying the host cells. The presence of inositol, at least in the case of RSV, results in increased amounts of infectivity either by protection of virus against desiccation death or by some other mechanism.

As already discussed, evidence has been obtained for a mutational effect of desiccation on bacteria<sup>10,13,16,21</sup>. In conjunction with the demonstrations of increased virus release and survival it was felt that experiments with dried normal cells should be undertaken. Initially, pooled spleen cells were obtained from 1-year-old Swiss mice by gentle homogenization and straining through 4 layers of sterile gauze. After centrifuging, half the cells were re-suspended in BSS and the other half in 5 per cent inositol solution. Approximately  $2 \times 10^7$  cells were pipetted on to 60-mm Petri dishes and allowed to settle

for 2-3 h at 37° C. The supernatant fluid was removed and the cells were dried in the humidifier cabinet for 30 min at RH 70 per cent. The dried cells were re-suspended in BSS or 5 per cent inositol for inoculation and samples of non-dried cells were saved for inoculating control groups. Groups of 8-week-old female Swiss mice were inoculated intraperitoneally with about  $5 \times 10^5$  cells, and in addition to the non-dried cell controls other groups were given BSS or 5 per cent inositol solution. The experiment was allowed to run for 12 months after which time all the survivors were killed and autopsied. Sections were prepared from all animals not autolysed. Since little or no difference in tumour incidence appeared between the groups treated with cells dried in BSS and those treated with cells dried in inositol, the groups were combined for simplicity of presentation in Table 2 (Exp. 1). Two animals died during the experiment, one with lymphoblastic leukaemia and one with mammary carcinoma. Both of these were found at autopsy and confirmed histologically. It is apparent that the inoculation of dried spleen cells resulted in an increased incidence of tumours. The final column shows the total number of tumours scored. Some animals developed both leukaemia and mammary carcinoma and both conditions appeared in greater numbers in the group given dried cells.

All the leukaemias appearing in these animals were diagnosed either as lymphoblastic, involving the thymus, lymph nodes, liver, kidney and, usually the spleen, or as mixed lymphoblastic-lymphocytic in which similar but less extensive organ involvement was observed. It has already been mentioned that most of these tumours were found at autopsy 12 months after inoculation of the spleen cells. Attempts to reduce the latent period of leukaemia by transplantation of homogenates of affected organs have not so far been successful. However, it was noted in many instances that the mice receiving the dried spleen cell preparations developed a strong plasma cell reaction with abdominal ascites formation within 4 weeks after inoculation. This occurred in both adult and new-born mice whether the cells were given intraperitoneally or subcutaneously, and was usually accompanied by splenic enlargement. The reaction subsided over the following 2-3 weeks, but marked plasma cell infiltration of lymph nodes, liver, kidney and spleen persisted until the animals were killed at the end of the experiment. Close inspection of the plasma cells in the ascites fluid of many such animals failed to reveal signs of malignancy, but pooled fluid from 2 mice at the height of the reaction was nevertheless transferred to another group of 8-week-old mice along with homogenized spleen and liver from the same animals to make a 1:10 cell:fluid suspension. All the recipient animals developed marked ascites and splenomegaly within 3 weeks and, again, fluid plus spleen and liver cells was transferred to a third group. All animals again developed marked reactions similar to those seen in the previous passages. No evidence of bacterial contamination and transfer was found. The survivors were left for 12 months to see whether the incidence of tumours was altered by the serial transplantation of these cells. The results are presented as Exp. II in Table 2. It can be seen that the incidence of tumours increased at each passage. Again the final column indicates that some animals developed both leukaemia and mammary car-

Dried RH 30 per cent	9	0	0

\* Figures in brackets indicate number of leukaemias (L), mammary carcinomas (MO) or ovarian carcinomas (OO).

cinoma. It is interesting to note that a high incidence of mammary tumours was only observed in the group inoculated with dried cells and that most of the increased tumour incidence in subsequent passages was due to leukaemia. It should also be noted that the previous experiment also showed high mammary tumour incidence in the group given dried cells. As before, most of the tumours were found at autopsy and did not kill the animals within the 12-month time limit of the experiment. Only 2 mice died with tumours during the experiment, one from the second passage at 19 weeks and one from the third passage at 33 weeks. Both of these were diagnosed as lymphoblastic leukaemias.

Since most of the leukaemias developing in these mice were of the lymphoblastic type an experiment was undertaken in which thymus cells from apparently normal 2-month-old Swiss mice were dried before inoculation into new-born mice. In view of the accumulated data from bacterial studies, which suggested that maximum biological changes when drying were found at low RH levels, 3 groups of new-born mice were inoculated with pooled thymus cells dried for 30 min at RH 60, 40 and 30 per cent, respectively, in the absence of inositol. The cells were prepared as before by gentle homogenization and straining through 4 layers of sterile gauze. Drying was carried out in Petri dishes with approximately  $10^7$  cells in the chemical drying chamber, and controls were inoculated with untreated cells from the same pool. Again the survivors were killed after 12 months and the final results are presented in Table 3.

It is apparent from the final column of Table 3 that the incidence of leukaemia in the groups given cells dried at RH 40 and 60 per cent was higher than in the controls. None of the animals given cells dried at RH 30 per cent developed tumours, which suggests that all biological activity had been destroyed. This is not surprising in view of previous results with bacteria and viruses. That activity survived drying to RH 40 per cent might appear surprising, but may be explained by the lack of precise humidity control that can be more easily achieved with bacterial aerosols. Another important feature of these results is that 4 of the 7 animals which developed tumours with 40 per cent dried cells did so before the 12-month

time limit. The earliest (19 weeks) developed an ovarian carcinoma as well as lymphoblastic leukaemia, the former being an extremely rare tumour in our colony. It is also interesting to note that the inoculation of thymus material did not result in a high incidence of mammary carcinoma.

Two biological phenomena associated with desiccation, namely, changes in function (mutation) and release of infectious viruses, led to the idea that carcinogenesis might be the occasional result of such changes in animal cells. There seems no doubt that in the preliminary experiments so far undertaken, the removal of molecular bound water from normal cells can result in the production of carcinogenic potentialities. Thus desiccation may be classed with carcinogenic chemicals, radiation and other tumorigenic agents, and the concept furthermore provides an attractive basis for a more general hypothesis of the mechanism of carcinogenesis. The removal of structurally important water could be accomplished by chemical means or by radiation. Local dehydration could also result from the implantation of plastics and other chemically inert materials. Tissue desiccation in old age could conceivably result in bonded water exchange with the environment, thus favouring the conditions necessary for a critical water loss. The macromolecular structural changes occurring in cells under these conditions result in marked changes in biological function, including mutation, virus release and death. Carcinogenesis could occur as a result of the production of viable mutated cells or, more probably in view of the apparent destruction of Ehrlich ascites cells, as a result of virus release or the appearance of altered, genetically competent macromolecules.

## ACTION OF ACETYLCHOLINE ON COCHLEAR RESPONSES

By YASUJI KATSUKI, YASUO TANAKA and TAMOTSU MIYOSHI\*

Department of Physiology, Tokyo Medical and Dental University, Yushima, Bunkyo, Tokyo, Japan

RECENT work, using the electron microscope, has shown that cochlear hair cells are synaptically connected with nerve endings, of which two different types have been demonstrated by Smith and Sjöstrand<sup>1</sup> and by Engström and Wersäll<sup>2</sup>. In 1959, Schuknecht *et al.*<sup>3</sup> investigated the localization of acetylcholinesterase in the cochlea of the cat and suggested that efferent nerve fibres in the olivo-cochlear bundle had high acetylcholinesterase activity. Hildings and Wersäll<sup>4</sup> reached a similar conclusion. Galambos<sup>5</sup> has shown that electrical stimulation of crossed efferent fibres in the olivo-cochlear

bundle diminishes the action potentials of the whole cochlear nerve, and Fex<sup>6</sup> has reported that the cochlear microphonics increase in amplitude. In a pharmacological investigation, however, Deamett and Monaco<sup>7</sup> have obtained results showing that strychnine and brucine can suppress these centrifugal effects of electrical stimulation in the olivo-cochlear bundle; but anticholinesterase cannot suppress them. This suggests that a kind of inhibitory transmitter substance, which is ineffective in the presence of strychnine, plays an important role in a feedback mechanism in the cochlea. Thus, there are some complexities in considering neurophysiological results on the basis of histochemical findings on the organ of Corti.

\* Present address: Department of Oto-Laryngology, Tohoku University, School of Medicine, Sendai, Japan.

In order to clarify such divergent experimental results, pharmacological agents were applied ionophoretically to the vicinity of cochlear hair cells. Eighty-nine guinea-pigs were used, and responses in the primary auditory neurones and the electrical stimulation of efferent nerve fibres were obtained from 22 cats.

The cochlear microphonics (CM) and the neural component  $N_1$  were recorded by means of vestibulo-tympanic leads from the basal turn of the cochlea. In recording single-fibre responses in cat, the flocculus of the cerebellum was retracted dorso-medially, and a capillary ultramicro-electrode was inserted into the cochlear nerve at its entrance into the internal auditory meatus.

Simultaneously with the recording of cochlear responses to sound, a capillary electrode with a tip diameter of  $2\mu$  was inserted into the hair cell region through the round window. The negative resting potential in the organ of Corti was considered as indicating penetration of the basilar membrane. Ionized chemical agents contained in the capillary were administered ionophoretically in the vicinity of the hair cells by means of a  $10^{-6}$  amp electric current in the form of a square wave, 500 msec in duration, applied at a frequency of once per sec for 8–10 min. The efferent nerve fibres were stimulated by electrodes placed in the floor of the fourth ventricle after removing the cerebellar vermis by suction.

The application of inorganic ions such as sodium, potassium and chlorine had no effect on the CM and  $N_1$  responses. Fig. 1 indicates that the CM and  $N_1$  were not influenced by potassium ions in  $8 \times 10^{-6}$  amp current. In contrast with the results for inorganic ions, acetylcholine (ACh) or prostigmine elicited gross changes in the cochlear responses. The CM decreased abruptly in amplitude during or shortly after ACh administration using the same amount of anodic current used for ionophoresis of the potassium ions, as shown in Fig. 1. However, separate administration of ACh or prostigmine diminished the amplitude of the CM to less than 50 per cent, usually within 20 min after the beginning of iono-

phoresis. Other drugs have been similarly tested but with negative results. Application of  $\gamma$ -aminobutyric acid (GABA), which is known to inhibit excitatory synapses in the cat brain, had no effect on this preparation; normal CM and  $N_1$  responses were maintained for as long as 120 min after applying the ionic current. Administration of strychnine produced no consistent change in the CM and  $N_1$  responses, apart from its effect in the olivo-cochlear inhibition as shown by Desmedt and Monaco. Local applications of adrenaline and atropine had no effect on the cochlear responses.

Since change in the  $N_1$  response due to ACh was not as obvious as that in the CM response, it was necessary to observe unitary response of the primary auditory neurones. The firing rate of fibres with characteristic frequencies above 5,000 c/s began to decrease first during the administration of ACh. This effect tended to extend gradually toward the low-tone frequency range, probably due to the diffusion of the ACh over the basilar membrane.

Other studies demonstrate that the action of ACh is blocked by curarization. As shown in Fig. 2, the applica-

Fig. 1. Effect of ionophoretic application of acetylcholine on cochlear responses (administrations of potassium and acetylcholine have been combined). Photographs illustrate the cochlear microphonics and neural component  $N_1$  responses recorded from the basal turn of guinea-pig. Potassium ions were applied with electric current,  $8 \times 10^{-6}$  amp from 0 to 10 min, and acetylcholine, 85 to 95 min. Abscissa, time in min. Ordinate, amplitude of the cochlear microphonics response (open circles—4, 7 and 11 kc) and the  $N_1$  response (filled circles) in millivolts.

Fig. 2. Effect of acetylcholine application to curarized 'organ of Corti'.  $d$ -Tubocurarine was applied with current  $4 \times 10^{-6}$  amp from 0 to 10 min, and acetylcholine with  $8 \times 10^{-6}$  amp, 85 to 95 min. Cochlear microphonics to 4, 7 and 11 kc pure tone stimuli (open circles),  $N_1$  (filled circles).

tion of  $d$ -tubocurarine in  $4 \times 10^{-6}$  amp of current causes a gradual reversible decrease of the CM and  $N_1$  responses. When ACh was applied during this recovery the cochlear responses were only very slightly depressed even with twice the amount of ionic current that was used with  $d$ -tubocurarine. It is very significant, as compared with change of the CM and  $N_1$  responses to the ACh phoresis in Fig. 1, that ACh fails to diminish cochlear responses after administration of  $d$ -tubocurarine. Although Eccles *et al.*<sup>6</sup> have reported that intravenous injection of dihydro- $\beta$ -erythroidine (DHE) reduces the sensitivity of the Renshaw cell to ACh, 1–5 mg/kg of the DHE, enough to relax the respiratory muscles, did not influence the ACh effect on the cochlear responses.

Electrical stimulation of the crossed olivo-cochlear bundle inhibits neural response in the cochlea and augments the CM. This inhibitory effect is suppressed by intravenous injection of strychnine, in accordance with the results described here. When  $d$ -tubocurarine was applied to the hair cell region the amplitude of the  $N_1$  response was still reduced by as much as 15 dB attenuation of the

Fig. 3. Comparison of effects of strychnine and *d*-tubocurarine on olivo-cochlear inhibition. These photographs illustrate the  $N_1$  responses to sound (click, 40 dB) and the cochlear microphonic responses (3.5 to pure tone, 40 dB) recorded from the left round window in cat. 2. Electrical stimulation on the olivo-cochlear bundle at the floor of fourth ventricle, the bundle was stimulated with square wave 0.1 msec at 200/sec. Strychnine was applied intravenously and *d*-tubocurarine, ionophoretically in  $8 \times 10^{-4}$  amp current. 1, Before, and 2, 2 sec after the electrical stimulation.

tone stimuli by electrical shocks to the efferent fibres, as shown in Fig. 3.

It has not previously been recognized that the administration of ACh in the cochlea produces any effect there. In this experiment various ionized chemical agents were applied ionophoretically to the hair cell region; only ACh and anticholinesterase were effective. This is considered in relation to histochemical findings showing that the organ of Corti has intense cholinesterase activity, as reported by Schuknecht and Wersäll.

The effect of ACh on the nerve ending is generally known to be excitatory, in other words ACh depolarizes the membrane of the postsynaptic ending. But there has so far been no sign of excitatory effect there in the case of recording the responses of the single primary neurone to sound stimulation. It is therefore supposed that a part of the hair cell membrane is sensitive to ACh, since anticholinesterase acts like ACh to decrease the CM, and the ACh effect is prevented by curarization. Intravenous injection of DHE did not block the ACh effect. If cochlear potentials are cholinergically controlled, it would be expected that the ACh effect on the cochlear responses would be changed somewhat by systematic injection of DHE, as occurs in the central nervous system. It is imagined that the cochlea has a different blood barrier to DHE, but there is no evidence of it in this experiment. The ionophoretic application of *d*-tubocurarine did not influence the inhibition of the  $N_1$  response elicited by electrical stimulation of the crossed olivo-cochlear bundle. Recent experimental results show that strychnine suppresses the inhibitory action of both crossed and uncrossed efferent nerve bundles.

Consequently the results permit the conclusion that the efferent nerve fibres to the cochlea are not cholinergic, though acetylcholine depresses the activity of hair cells to a remarkable extent.

## ELECTROPHYSIOLOGICAL EVIDENCE FOR OLFACTORY FUNCTION IN BIRDS

By DON TUCKER

Department of Biological Sciences, Florida State University, Tallahassee, Florida

IN describing the well-developed olfactory organs of some birds, Bang<sup>1</sup> criticizes the tendency to perform olfactory learning investigations on "feebly equipped" or "poorly endowed" birds such as pigeons, and justifiably concludes that these prove nothing about birds with "superior receptors". Concerning the turkey vulture, oilbird and albatross, she writes, "It is apparent that no definitive controlled experiments on the function or sensitivity of the chemoreceptors have been done".

It is now possible to record electrically the impulse traffic in the axons which comprise the primary olfactory nerve. The dorsal space between the eyes of most adult birds is occupied by spongy bone which is easily removed to leave a cavity bounded by orbital walls of thin bone, through which one can see the olfactory nerves. In the nighthawk (a goat-sucker) the posterior half of each nerve traverses the cavity, sheathed in a thin tube of transparent bone. After closing off connexions to the air spaces with bone wax and exposing a nerve, Ringer's solution is introduced to facilitate the neural twig dissection. The method is similar to that described for the gopher tortoise (*Gopherus polyphemus*)<sup>2</sup>. Although it is not really difficult to free small, live twigs of the bird's olfactory nerve, at first I found it difficult to perform the dissection without more stretching than is tolerable for some other animals. I discovered that useful results may be obtained by lifting the whole nerve up on the recording electrodes. Thus, it seemed sensible to search for a bird so feebly

equipped that its nerve bundle would fall in the desired diameter range of 10–100 $\mu$ . However, I have seen no olfactory nerves nearly so small in birds, but the nerve twigs seem to be unusually resistant to the effects of stretching, unlike rabbit olfactory nerve, for example. There is often a curious delay of several minutes before a preparation exhibits responsiveness, but once it develops the preparation is usually stable for many hours. This type of stability is distinct from the occasional appearance of a phenomenon which appears to reflect the reflex changing of accessibility to the olfactory organ. Table 1 lists species of birds in which successful olfactory receptor preparations were made.

We have recorded responses to odorants in various species of mammals, amphibians and reptiles as well as birds. The lack of obvious species differences has impressed us, since in the examination of taste with similar methods, species differences are readily apparent<sup>3,4</sup>. In these methods the neural electrical activity is continuously averaged with an integrator circuit of relatively short time constant. Thus, the magnitude of response is recorded directly, in deflexion units proportional to the number of nerve impulses per unit time. The olfactory responses occur in bursts synchronized with inspirations, but normally there is never a complete absence of neural activity, even with the cleanest air that we have been able to prepare. Such response records are shown in Fig. 1 for the sparrow hawk, goose, black vulture, chicken and, for

Table 1. BIRDS FROM WHICH OLFACTORY RECORDS WERE OBTAINED

Common name	Specific name	Body-wt.
Blue jay	<i>Cyanocitta cristata</i>	53-70 g
Common nighthawk	<i>Chordeiles minor</i>	80
Yellowthroat (warbler)	<i>Geothlypis trichas</i>	8-8
House sparrow	<i>Passer domesticus</i>	22
Ring-billed gull	<i>Larus delawarensis</i>	440
Chicken (white leghorn)	<i>Gallus gallus</i>	330-930
Sparrow hawk	<i>Falco sparsarius</i>	100
Homing pigeon	<i>Columba Hous</i>	360
Bob-white quail	<i>Coturnix virginianus</i>	170
Emden goose	<i>Anser anser</i>	4,100
Black vulture	<i>Coragyps atratus</i>	1,900-2,200
Turkey vulture	<i>Cathartes aura</i>	1,900
Muscovy duck	<i>Cairina moschata</i>	1,700-2,900
Common crow	<i>Corvus brachyrhynchos</i>	870-900

Olfactory records were obtained from these birds, listed chronologically, by the first specimen where a group is indicated by a range in weight.

comparison, rat. The chicken and goose might have been inspiring quickly enough to draw some room air into the breathing chamber, so the high background activity might be artefactual. Because the olfactory response is a function of the inspiratory flow rate, as well as of the kind of odorant and its concentration, the records reflect differences in inspiration and in the time of the respiratory cycle when the stimulus was exchanged for the clean air flowing through the breathing chamber. A few movement artefacts are evident in the first and last traces. Apart from the effect of differences in respiratory rhythm, the results were quantitatively similar for the two higher log units of concentration not shown in the figure. The olfactory receptors adapt considerably and rapidly at the highest concentration of amyl acetate.

The evidence indicates that the olfactory response as recorded from a small population of the receptors is quantitatively similar for diverse birds and other air-breathing animals. Birds were tested with various odorants without control of the stimulus concentration, as was done for amyl acetate, and in no instance was the nasal flow rate controlled, but the results were remarkably similar among the species. We appreciate the anatomical descriptions by Bang and recognize that the foregoing quotations, which imply superiority of the receptors in some species, might have been meant to apply collectively, for the organ. But the undoubted differences in olfactory performance of animals seem likely to be correlated with the extent of development of the olfactory apparatus, as Bang emphasized. However, the 8-g warbler might be the

olfactory equal of the 4,000-g goose (Table 1); thus a relative measure such as the ratio of bulb to cerebral hemisphere diameters used by Cobb<sup>8</sup> is probably pertinent.

Why the possession of a greater number of olfactory receptors should confer on an organism a heightened olfactory faculty, as is often implied, is not at all clear, since a relatively small number should be sufficient, in theory. Neuhaus<sup>9</sup> considered the sensitivity aspect of this question *vis-à-vis* the possibility of major differences in the sensitivity of receptors of related species. His discussion, however, rests heavily on the proposition that dogs have a much lower concentration threshold for butyric acid than do rats or humans, and not many more receptors. The influence of size and of three-dimensional folding and pocketing of the receptor sheet on quality discrimination and sensitivity was discussed by Adrian<sup>7</sup>: "We can see therefore why the dog should have a much larger and more elaborate organ than the rabbit. There is no reason why a large organ should be more sensitive to smells than a small one, but it will certainly provide a screen on which the pattern of excitation can be mapped in greater detail". His 'sensitivity' of the organ is logically not the same as the behavioural 'sensitivity' of Neuhaus, although it is the basis of it. Later, Adrian<sup>8</sup> emphasized the importance of differential receptor sensitivity for olfactory quality discrimination, but still maintained the likelihood that an animal obtains useful information from differences in the areal and temporal distribution of excitation of the organ by different odours. However, we are led to the idea that the olfactory stimulus is attenuated as it penetrates to the more inaccessible locations of the organ. Suppose that the electrophysiologist leads signals from a sample of receptors that includes some of a group most responsive to the odorant being used and that he controls the stimulus conditions enough to deduce the effective stimulus at those receptor sites<sup>8</sup>; the receptor sensitivity function determined in this way should constitute a limit for behavioural performance. Although the data shown in Fig. 1 do not yield this information, it is interesting that the differences are relatively so small among the species. The one that is obviously different correlates with the greater nasal complexity of the rat, though the relative stimulus attenuation in this instance is only about one half log unit, or a factor of three.

Neuhaus's<sup>9</sup> training experiments with various birds were fruitless. However, he succeeded in demonstrating changes in respiration of the goose on the presentation of odour. The possibility of trigeminal activation was considered. Although we have not yet studied trigeminal responses in birds, the threshold concentration of amyl acetate for the trigeminal receptors of the gopher tortoise and rabbit is near the relatively high value of 10 per cent saturation at 20° C. As Adrian<sup>8</sup> noted, rabbits under urethane anaesthesia seldom change their respiration with odours little above olfactory threshold values. In contrast to the mammals, birds and reptiles often exhibit reflex changes on breathing amyl acetate at concentrations lower than the trigeminal threshold cited here. The records in Fig. 1 show respiratory acceleration of the sparrow hawk and chicken at 1 per cent or less of saturation. It is notable that these reflexes persist in the anaesthetic state. Thus, we can conclude with Neuhaus that there probably exist innate reflexes mediated by the olfactory apparatus.

Reports vary as to the olfactory learning ability of birds<sup>10-12</sup>. I am convinced that the olfactory systems of birds are functional and, further, I emphasize how difficult it is to imagine that such functionality might

Fig. 1. Primary olfactory nerve responses to amyl acetate breathed in air at concentrations expressed as exponential fractions of vapour saturation at 20° C. Odour was presented every 3 min for durations of 1 min in the first trace and 0.5 min in the others. Records were processed with a Sanborn model '350-1,400' amplifier on the AO LINEAR mode of operation, for which the output indication is 'full wave average'.

persist without biological significance. That significance may be unlike our own subjective sensation of smells, because of the vast differences in mammalian and avian nervous systems, as Cobb and Neuhaus stressed. Some of the avian experimental preparations seem especially well-suited to the experimental needs of the electrophysiologists (see also Stager's<sup>14</sup> dissertation on the role of olfaction in food location by the turkey vulture).

## AN UNEXPECTED ARTEFACT IN THE HUMAN ELECTROENCEPHALOGRAM CONCERNING THE ALPHA RHYTHM AND THE ORIENTATION OF THE EYES

By DR T. MULHOLLAND and DR C. R. EVANS

Autonomics Division, National Physical Laboratory, Teddington, Middlesex

THE alpha component of the human electroencephalogram is one of the most commonly measured rhythms and its relationship to such factors as 'attention', visual input, and cognitive activity has been the subject of considerable investigation<sup>1</sup>. Summarizing a complicated and often somewhat confused field, the consensus of scientific opinion at present is that the optimum conditions for observing alpha occur when the individual is relaxed, with eyes closed, and neither drowsy nor alert. Under these conditions, present theory maintains that the characteristic alpha rhythm reflects synchronous fluctuations of dendritic potentials associated with a very large sample of cortical cells. The assumption is now general that by observing changes in alpha occurrence, inferences can be made as to the subject's degree of alertness, or to such matters as whether or not he is processing visual information. The results reported here, however, suggest that such assumptions may no longer be held with confidence, and that a variable as fundamental as the orientation of the eyes may drastically alter the probability of alpha occurrence.

The results were obtained from two male subjects, both of whom exhibited abundant 'resting' alpha. The electroencephalogram was recorded unilaterally using bipolar parietal-occipital scalp electrodes. The experiment was suggested as the result of chance observations made during a separate study by one of us (T. M.), who noticed that there appeared to be a marked increase in the occurrence of alpha when the eyes were rolled upwards. At first it seemed probable that this effect was due to the sharp reduction in visual input which occurs when the eyes are in this elevated position, despite the obvious increase in effort and 'attention' that maintaining this position involves. When it was noted, however, that the effect was maintained in dim illumination, it was decided to introduce appropriate experimental controls.

In the first phase of the experiment, alpha was recorded in normal room illumination and a comparison was made between the classic 'eyes open-eyes closed' test, and the

'eyes ahead-eyes up' phenomenon. Subjects were given ten 30-sec trials in each condition, the experimenter giving the command 'eyes open', followed in 30 sec by the command 'eyes closed', etc., or by the commands 'eyes ahead' followed by 'eyes up'.

The electroencephalogram was evaluated according to the presence or absence of alpha, this being defined in the resting record as a signal having a frequency of 8-13 c/s amplitude greater than 30  $\mu$ V. In the experimental conditions a rhythm was identified as 'alpha' when it was greater than 40 per cent of the average resting alpha amplitude. Despite the crudeness of the measures used, the magnitude of the effect was sufficiently great to render any more precise a criterion unnecessary.

Fig. 1 illustrates the changes in the EEG which occur when the eyes are moved from a straight ahead position to the elevated position. Table 1 illustrates the mean percentage of time for which alpha was present in the various conditions.

In the second phase of the experiment the previous conditions were repeated with the exception that the eyes were always covered to prevent patterned visual input. Table 2 summarizes the results.

It is evident from Tables 1 and 2 that there is an increase in alpha in the 'eyes up' condition, though this appears to be less in the case of subject R. R. than subject T. M. However, at this stage these results might yet be interpreted as showing that the effect of elevating the eyes is to

Fig. 1. Characteristic parietal-occipital EEG recorded from subject T.M. when eyes were elevated ('up'), or in normal straight-ahead position ('ahead'). Arrows indicate approximate time of shift of eye position.

Table 1

	T.M.	R.R.
Eyes open	7%	3%
Eyes closed	84%	88%
Eyes ahead	9%	4%
Eyes up	86%	75%

Table 2. EYES COVERED

	T.M.	R.R.
Eyes open	53%	63%
Eyes closed	79%	69%
Eyes ahead	18%	50%
Eyes up	81%	53%

reduce either: (a) overall illumination, or (b) overall patterned visual stimulation, and that it is not eye position *per se* that is the important variable. In the third and fourth phases of this experiment, an attempt was made to clarify these points.

(a) *Overall illumination.* If the increased alpha is a function of a decrease in effective overall illumination, then a simple control would be to introduce diffuse but intense illumination whenever alpha occurs, whether in the 'eyes ahead' or 'eyes up' condition. Such a closed-loop between stimulus and EEG has been described elsewhere<sup>2</sup> and such a system was used here. In effect, the occurrence of alpha turned on a brilliant light, flooding the visual field; this light was automatically extinguished when alpha disappeared. Table 3 illustrates that despite the coupling of a bright light to alpha, its occurrence in the 'eyes up' condition was very high and the remarkable differential between the two conditions was maintained.

	T.M.	R.R.
Eyes ahead	8%	41%
Eyes up	90%	48%

(b) *Patterned stimulation.* If, on the other hand, the increased alpha is a function of a decrease in overall 'patterned' stimulation, then further examination is necessary to clarify this point. The complications of ensuring that the subject receives patterned stimulation when his eyes are rolled up are simply overcome by the use of a patterned after-image. The basic method has been previously used in EEG investigations and is described in full elsewhere<sup>3</sup>. Simply put, subjects were given a brilliant after-image of a pattern (a circle with an inscribed cross), subtending approximately five degrees and foveally fixated. This could be readily perceived as a pattern by subjects for a full minute after the flash whether the eyes were in the 'ahead' or the 'up' position. Because of the relative impermanence of the after-image it was not possible to conduct 5-min trials as in the previous experiments. Shorter trials each of two 30-sec runs were therefore performed controlling for sequence. Eyes were closed and covered immediately following the flash, and subjects were then given the appropriate commands. Table 4 illustrates the mean percentage time for which alpha was present in the two conditions.

	T.M.	R.R.
Eyes ahead	18%	3%
Eyes up	28%	28%

It is clear that the patterned input has reduced the total amount of alpha present, but the differential between the 'eyes up' and 'eyes ahead' condition is maintained.

The relevance of these results to experiments involving the alpha component of the human EEG is obvious. It is clear that eye position is a significant variable which furthermore has been demonstrated to be sufficiently powerful to override such established variables as increments of homogeneous and patterned stimulation, normally quoted as markedly inhibiting alpha occurrence. In addition, as any individual may test for himself, keeping the eyes up not only involves continuous attention and muscular effort, but also becomes increasingly uncomfortable. Despite this combination of normally alpha-inhibiting conditions, more alpha occurs in this situation than in the comfortable, effortless 'eyes ahead' state.

These facts seem to suggest that a re-appraisal of the methods and design of human EEG experiments cannot long be delayed. This argument is rendered more stringent when one recalls that there is a tendency in the relaxed conditions prevailing when eyes are closed for the eyes to rotate upwards. Thus the classic 'eyes open'—'eyes closed' test for alpha (alpha normally appearing when eyes are closed) may not in fact reflect reduced visual input as has been almost universally supposed, but rather some such prosaic variable as the tendency for eyes to turn upwards under such conditions. Whether this is sufficient to account for all such differences seems unlikely, but it is now evident that: (a) much previous experimental work will need to be re-appraised with these facts in mind; (b) no experiments attempting to relate alpha presence or absence to such variables as 'attention' will be meaningful unless eye position is monitored in both the 'eyes open' and 'eyes closed' conditions.

In conclusion we will note that an extended series of experiments using a greater number of subjects is at present in progress. It is already clear that the effect already described may be found in marked fashion in 50 per cent of all subjects tested—though in some individuals its occurrence is less reliable than in others. A number of variables, such as subjects' general ability to hold their eyes continuously in any given position, no doubt contribute, and it is hoped subsequently to identify these variables. However, at the moment it seems unlikely that any 'screening' of individuals prior to their participation in an EEG experiment would be of much use, for the effect may suddenly appear in subjects who do not, on the first test, exhibit it.

Since performing the original experiments we have heard from Dr. M. D. Dewan, of the U.S. Office of Aerospace Research, who has independently observed that alpha occurrence is increased when his subjects were 'looking upwards' with eyes closed.

## DIRECT X-RAY INACTIVATION OF THE VIRUSES OF TESCHEN AND TALTAN DISEASES, FOOT-AND-MOUTH DISEASE AND VESICULAR STOMATITIS

By C. D. JOHNSON\*

Research Institute (Animal Virus Diseases), Pirbright, Surrey

THE inactivation of viruses by the direct effect of X- and γ-radiations has been shown by many workers to result in exponential survival curves from which it is possible to calculate the radiation-sensitive volumes of the virus particles<sup>1-4</sup>. Unfortunately, this calculation

requires a value for the density of the radiation-sensitive part of the virus and this is, in general, not known. However, using approximate values for this density, the sensitive volumes of several viruses have been determined, and those of the smaller viruses have proved to be numerically very close to the virus particle volumes as determined by other methods<sup>5,6</sup>. As a preliminary to the

\* Present address: J. J. Thomson Physical Laboratory, University of Reading.

investigation of the degradation processes involved in this form of inactivation, a comparison has been made between the direct X-ray inactivation rates of the following viruses: foot-and-mouth disease virus (FMDV) of two immunologically different types, strain *M.11*, type 0, and strain *BV.11*, type *SAT* 1 (ref. 7); vesicular stomatitis virus of the Indiana immunological type and two viruses of the Teachen disease group, the original Teachen (Konratice) strain which produces a polioencephalomyelitis in pigs in Europe and the Talfan strain which affects young pigs in Britain<sup>8</sup>. Cross-neutralization tests have indicated that the two strains may be regarded as different serotypes of the same virus<sup>9</sup>. The results which are described here show that it is not possible to differentiate between these two strains by observation of their rates of direct inactivation by X-radiation.

The virus materials used in these experiments were obtained from a variety of sources as follows: FMDV strain *M.11* (type 0) from virus propagated on cell monolayers grown from pig kidneys<sup>10</sup> or from the *BHK* 21/13 cell line derived from baby hamster kidneys<sup>11</sup>. The pig kidney cell monolayers were grown in Roux flasks and the baby hamster kidney cell monolayers as continuous layers in cylindrical 3-l. bottles rotating with their axes horizontal at one revolution in 4 min. FMDV strain *BV.11* (type *SAT* 1) was attenuated for cattle by serial passage first in unweaned mice and later in older mice<sup>12</sup>. The viruses of Teachen and Talfan diseases were propagated on pig kidney cell monolayers and vesicular stomatitis virus (VSV) was grown on the chorioallantoic membrane of 7-day-old developing chick embryos. The allantoic and amniotic fluids were collected and pooled 24 h after inoculation of batches of about 30 eggs.

A Raymax-150 industrial X-ray unit manufactured by Associated Electrical Industries, Ltd., was used as the source of X-rays. All irradiations were performed with lightly filtered 150 kVp radiation having a first half-value-layer thickness of 0.5 mm copper. One set of FMDV samples were irradiated in the frozen state at a temperature of approximately  $-80^{\circ}\text{C}$ . The virus in these samples was suspended in 0.1 M ammonium bicarbonate at pH 7.6 so as to minimize inactivation due to pH variations on change of phase. All other samples were irradiated in a 20 per cent w/v solution of peptone in phosphate-buffered saline at pH 7.6. This was a sufficiently high peptone concentration to prevent significant inactivation of the viruses by the indirect effect of free radicals and other radiation products in solution<sup>13</sup>. During irradiations these samples were maintained at temperatures between  $0^{\circ}$  and  $5^{\circ}\text{C}$ .

The frozen and some of the liquid samples were irradiated in 'Lustroid' tubes set in a copper cooling bar fitted with a 'Perspex' cap which incorporated the beam filter. This bar was thermally insulated from the X-ray tube housing to which it was rigidly fixed during irradiations. The samples in this particular container were irradiated at a constant dose-rate of 3,000 r.p.m. for various times. Other samples were irradiated in a 'Perspex' jig of helical form so that the dose-rates to the eight samples, held at various distances from the X-ray tube anode, varied from 130 to 1,600 r.p.m. The slopes of the survival curves were found to be independent of dose-rate, which confirmed that the indirect effect had been eliminated.

Irradiation doses were measured by the ferrous sulphate dosimeter modified by the addition of sodium chloride<sup>14</sup>.

After irradiation the infectivities of the virus samples were estimated by inoculation of series of ten-fold dilutions into groups of 5-10 unweaned mice<sup>15</sup>, or by plaque counts of ten-fold dilutions on pig kidney cell monolayers or on baby hamster kidney cell monolayers<sup>16</sup>. Further details are given in Table 1.

Table 1 and Fig. 1 summarize the results of these inactivation experiments. The survival curves of Teachen and Talfan viruses have equal slopes which are 30 per cent greater than that for the two FMDV types. It

Virus	Source of infective material	Method of infectivity titration	Size from electron microscopy (m $\mu$ )	Diameter of equivalent radiation sensitive sphere (m $\mu$ )
FMD type 0, strain <i>M.11</i>	Pig kidney (PK) and baby hamster kidney (BHK) cell monolayers	Plaque assay on PK and BHK cell monolayers	25, sphere	25
FMD type <i>SAT</i> 1, strain <i>BV.11</i>	Unweaned mice	Intraperitoneal inoculation of unweaned mice	25, sphere	25
Teachen and Talfan diseases	PK monolayers	Plaque assay on PK monolayers	35, sphere	35
Vesicular stomatitis type Indiana C	Pooled egg fluids	Plaque assay on BHK cell monolayers and intracerebral inoculation of unweaned mice	Bullet-shaped length 156-176 and diameter 60-70	39

is also apparent that the radiation sensitivity of the cattle attenuated FMDV (strain *BV.11*) has not been changed by passage in mice.

The size of the virus particle of FMD has been estimated by several observers<sup>17,18</sup> from results obtained by ultracentrifugation sedimentation analysis and by electron microscopy. The diameter of the infective component of this virus is in the region of 25 m $\mu$ . If we assume that the density of the radiation sensitive part of the virus particle is 1.35 g/ml. (ref. 3), the slope of the inactivation curve gives a value of 25 m $\mu$  for the diameter of the radiation-sensitive volume. As for other small spherical viruses, there is numerical agreement between these two sizes although this is probably a chance agreement depending on the finite range of interaction between a rather smaller sensitive volume and the radiation-induced ionizations in surrounding non-sensitive virus material. Nevertheless, it seems reasonable to suppose that a similar agreement will prevail in the case of the viruses of Teachen and Talfan diseases, for which a diameter in the region of

Fig. 1. Loss of infectivity of virus samples irradiated with lightly filtered 150 kVp X-rays:  $\circ$ , FMDV type 0, strain *M.11*;  $\bullet$ , FMDV type *SAT* 1, strain *BV.11*;  $\square$ , Talfan disease virus;  $\blacksquare$ , Teachen disease virus;  $\square$ , vesicular stomatitis virus.

28 m $\mu$  is indicated. This estimate of size depends on the assumption that the density of the radiation-sensitive volume is, in each case, the same as that of FMDV. Electron micrographs indicate that the diameters of the characteristic spherical particles of Teschen and Talfan diseases are both about 35 m $\mu$  (ref. 19).

The characteristic particle of vesicular stomatitis virus, as seen in electron micrographs, is bullet-shaped with a diameter of 60–70 m $\mu$  and a length of 155–175 m $\mu$  (refs. 20 and 21). The sensitive volume derived from the inactivation curve in Fig. 1 is that of an equivalent sphere having a diameter of 38 m $\mu$ . This is in agreement with a previous determination by Franklin<sup>22</sup>.

McCrea<sup>4</sup> has surveyed the irradiation data for a number of animal viruses, and he has shown that the size of the radiation-sensitive unit, which is close to its physical size for small spherical viruses, tends to a limit in the range 40–50 m $\mu$  for viruses larger than approximately 45 m $\mu$  diameter. The viruses investigated in the work reported here fit into this general scheme. Epstein<sup>23</sup> has demonstrated a close correspondence between the radiation sensitive volume and the nucleic acid content for a number of plant viruses and for phage T7. A similar correspondence may exist for these animal viruses.

Some preliminary results using the spray droplet counting technique with a polystyrene latex marker have indicated that the infectivity of FMDV is destroyed by the direct effect of X-rays without any immediate decrease in the concentration of characteristic particles. Virus samples which had lost up to 90 per cent of their original infectivity in mice or on cell monolayers, as a result of X-irradiation when frozen at  $-60^{\circ}\text{C}$ , showed no significant loss in numbers of characteristic particles counted in electron micrographs.

It was also observed that FMD virus samples, irradiated in aqueous solutions which contained lower protein concentrations than that required to protect fully from the indirect effects produced by inactivating agents generated by ionizations in solution, showed a loss of characteristic particles in proportion to their loss of infectivity.

The different sensitivities of the virus to changes in morphology, in relation to loss of infectivity, are not

unexpected on account of the dissimilar nature of the two inactivation processes, that is, the direct and indirect effects. The latter is the result of interactions between the virus and radiation products in solution. It is thought that there are many such interactions for every one which causes an inactivation<sup>24</sup>, and it is quite possible for the virus to be degraded more quickly under these circumstances than when suffering only direct ionizations which individually, although capable of destroying the virus infectivity, are apparently not sufficient to break up the particle itself.

I thank Dr. C. J. Bradish for his advice, Miss H. E. N. Ferrier for supplying vesicular stomatitis virus, Mr. B. J. Kirkham for the electron microscopy, and Mr. M. Ryat for his assistance.

## LOW-FREQUENCY TARGET STRENGTHS OF PILCHARD SHOALS AND THE HYPOTHESIS OF SWIMBLADDER RESONANCE

By B. S. McCARTNEY, A. R. STUBBS and M. J. TUCKER

National Institute of Oceanography, Wormley, Godalming, Surrey

ECHOES from pelagic fish shoals off the Cornish coast were detected in June 1964 using a 'Boomer' as a sound source<sup>1</sup> and a line hydrophone receiving array towed by R.V. *Olione*. The peak energy of the 'Boomer' sound source occurred between 1,100 c/s and 1,800 c/s. By comparing the shoal echo with the bottom echo and assuming extreme values for the bottom backscattering coefficient, an approximate range of values for the target strength or acoustic sectional area ( $\sigma_s$ ) of the shoal around 1,400 c/s was calculated. The results for three shoals are given in Table 1.<sup>2</sup> Fish caught at the time using an Engel midwater trawl were almost exclusively pilchards 21–25 cm long. These fish have gas-filled swimbladders equivalent in volume to approximately 2-cm diameter spheres.

The acoustic cross-sectional area ( $\sigma_f$ ) of a single fish is strongly dependent upon wave-length (or frequency); for wave-lengths much shorter than the fish dimensions (the geometrical scattering region) it is well known<sup>3</sup> that the echo strength is very variable and strongly aspect-dependent; at very long wave-lengths no measurements are available, but it is expected that Rayleigh scattering

applies and so the acoustic cross-section is proportional to  $\lambda^{-4}$ . For fish without swimbladders the Rayleigh scattering region and the geometrical regions merge at wave-lengths comparable with the fish dimensions. It is reasonable to suppose that a swimbladder might exhibit volume resonance in the same way as a free gas bubble in water<sup>4</sup>, and thus have a magnified and omnidirectional acoustic target strength at a frequency well below the geometrical scattering region. At the depth observed the pilchard's swimbladder would resonate between 500 c/s and 600 c/s, but at these frequencies there was insufficient signal-to-noise ratio for a reliable measurement. The measurements were at more than an octave above the theoretical resonance, but still more than a decade below the geometrical region.

When the fish are sparsely distributed, the target spectrum of the complete shoal will probably have the same form as that of a single fish and an intensity in proportion to the number of fish in the shoal. This number has been calculated for: (a) Rayleigh scattering by each fish assuming no resonant effect from the swimbladder;

Table 1

Shoal	Apparent depth* of shoal (m)	Depth of bottom (m)	Ratio of energy in bottom echo to energy in shoal echo over the band 1100 c/s to 1800 c/s	Acoustic cross-section of shoal $\sigma_s$ (m <sup>2</sup> )		Number of fish in shoal, $N_f = \sigma_s/\sigma$ assuming:			
				(I)	(II)	Rayleigh scattering $\sigma_f = 10^{-8}$ (m <sup>2</sup> )		Resonant scattering $\sigma_f = 1.25 \times 10^{-8}$ (m <sup>2</sup> )	
						(I)	(II)	(I)	(II)
1	24	51	90	0.84	2.5	$8.4 \times 10^8$	$2.5 \times 10^8$	$6.7 \times 10^8$	$2.0 \times 10^8$
2	24	41	12	12	87	$1.2 \times 10^{10}$	$2.7 \times 10^{10}$	$1.0 \times 10^8$	$3.0 \times 10^8$
3	28	49	11	15	44	$1.5 \times 10^{10}$	$4.4 \times 10^{10}$	$1.2 \times 10^8$	$2.5 \times 10^8$

Columns (I), assuming bottom back-scattering coefficient at normal incidence = 0.3; columns (II), assuming bottom back-scattering coefficient at normal incidence = 0.9.

\*Due to the wide lateral beamwidth of the line array, the apparent depth may not be the true depth.

(b) scattering on the assumption that each fish swim-bladder resonates at 500 c/s. Only case (b) gives a credible number of fish in each shoal.

When the fish are densely packed the target area of the shoal will also depend on the concentration. The transition from sparse to dense packing occurs when the acoustic cross-sectional area of one fish begins to overlap that of a neighbour and interaction may occur. Both for Rayleigh scattering and for scattering at an octave above resonance, packing densities required to cause interaction become unrealistic, but at the resonant frequency itself this may not be so.

The pilchard shoals were detected by a higher frequency (30 kc/s) echo-sounder, together with other shoals (probably mackerel) at shallower depths than the pilchards and also more disperse pilchard larvae over a large depth range. It is significant that the mackerel, which do not have swimbladders, and the larvae, whose small swimbladders resonate about 30 kc/s, were not observed on the low-frequency Boomer records.

Though it is acknowledged that the values are only approximate, the measurements are believed to be unique since they were taken at a frequency more than a decade below the geometrical scattering region. The results are important since resonance, if observed directly on a wide-band echo-sounder or fishing sonar, may be used to provide classification of the shoals into size, number and possible species of fish. It is intended to repeat the observation this year using a Boomer modified to cover the expected resonance region. Controlled experiments to determine the echo spectral response of single fish at and just above resonance present severe instrumental problems which have not yet been satisfactorily solved.

We thank the staff of the Fisheries Laboratory, Lowestoft, for their co-operation, and the master and crew of R.V. *Olimos* for their assistance.

## EFFECT OF RIBONUCLEASE ON ANTI-TUMOUR ACTIVITY OF RIBONUCLEIC ACID FROM NORMAL TISSUES

By N. N. AKSENOVA, Ju. B. VAKHTIN, V. I. VOROBYEV and Ju. M. OLENOV

Laboratory of Cancer Cytology, Institute of Cytology, Academy of Sciences of the U.S.S.R., Leningrad

SEVERAL authors have published the results of the anti-tumour effects of ribonucleic acids from normal tissues<sup>1-3</sup>. We have obtained similar results. The experiments were performed on the transplantable strain of liver mucous cancer obtained by Malugina. About 900 tumours were examined<sup>4</sup>.

Following on this work we found out that RNA preparations from normal tissues homologous to the tumours under investigation inhibited growth only in some of the tumour strains. But the results from single tests and experimental series even for these strains were found to differ greatly<sup>5</sup>. That is why we had to relinquish tumours of the Malugina strain on which the work recorded here had been started.

The difficulties which we met seem to be characteristic of many investigations aimed at revealing biological effects of RNA penetrating somatic cells from the outside. Thus when the question concerns the synthesis of the protein unusual for the cell it should be stated that this is induced by alien RNA (though not in all cases), or the level of it appears to be different<sup>6,7</sup>. It seems natural to suggest that these differences are due to changes in the competence of cell recipients. Unfortunately, it is difficult to say anything definite about this suggestion since the cause which conditions the state of competence was not known until now even in bacterial transformation, despite our knowledge of this process and homogeneity of the agent used (DNA)<sup>8-10</sup>.

There is another suggestion (it should not be considered an alternative) that the variability of the results is somehow related to the properties of the preparations used. In particular one cannot exclude the idea that the active component of the preparation is not RNA, but some unknown admixture extracted together with RNA from the tissue. The amount of these admixtures may be different in different tissues and also vary significantly in the preparations from one and the same normal tissue, thus determining the variability of the obtained effect. This article describes experiments performed to check this hypothesis.

Cells of the transplantable strain of rhabdomyosarcoma O 100-3/1 were used as recipients. The suitability of this strain for experiments of this kind has already been determined<sup>4</sup>. The strain O 100-3/1 is a progeny of the *in vitro* malignant cells (explanted cells of muscle tissues of new-born Wistar rats<sup>11</sup>). The strain was maintained in Wistar rats.

RNA was extracted from the bodies of rats 1-2 days old after removal of their paws, skin and viscera. The technique of removal has already been described<sup>12</sup>. One and the same preparation was used in 5 replications of the experiment (Table 1, II-VI); RNA was isolated from 3 groups of new-born rats. Combined sediment was obtained by ethanol reprecipitation. The preparation contained no DNA (tested by the method of Dische). The ratio of nitrogen/phosphorus was 1.63. The preparation contained glycoogen.

Table 1. EFFECTS OF INCUBATION FOR 10 H OF RAT RHABDOMYOSARCOMA C 100-3/1 CELLS WITH RNA PREPARATIONS EXTRACTED FROM MUSCLE TISSUE OF NEW-BORN RATS, ON THE WEIGHT OF TUMOURS 20 DAYS AFTER IMPLANTATION

Replication	Concentration (mg/ml.)	Control (incubation in Hanks's solution)		RNA			Additionally deproteinized RNA			RNase treated and deproteinized RNA		
		No. of animals	Average weight of tumours (g)	No. of animals	Average weight of tumours		No. of animals	Average weight of tumours		No. of animals	Average weight of tumours

VI	2.0	14	5.89	14	2.18	36.9	19	2.89	49.1	9	3.24	139.9
Total			5.65		1.35	23.9		2.5	36.3		3.70	65.5

Probabilities of differences, control—RNA, > 0.99; control—additionally deproteinized RNA, > 0.99; control—RNase treated and deproteinized RNA, < 0.05; RNA—additionally deproteinized RNA, < 0.05; RNA—RNase treated and deproteinized RNA, < 0.95. Additionally deproteinized RNA—RNase treated and additionally deproteinized RNA, > 0.95.

Before implantation the minced tumours C 100-3/1 were incubated with RNA in Hanks's solution with antibiotics at room temperature for 10 h following a previously applied technique<sup>4,12</sup>. Cells were injected subcutaneously; the weight of tumours was determined on the twentieth day. Each replication of the experiment had four variants. (1) The first variant (the control), incubation in Hanks's solution. (2) The second variant, incubation with RNA. (3) The third variant, incubation with RNA, treated with RNase at 37° for 1–2 h. The content of the enzyme was 15 µg/ml. RNase was removed by treatment with phenol four times. Phenol was extracted by ether. Nitrogen was blown through the solution to remove traces of ether. The solution was tested for RNase activity with freshly extracted liver RNA as a substrate. The increase in soluble nucleotides was measured by spectrophotometry. Such testing always yields negative results. (4) The fourth variant, incubation with RNA which was not treated with RNase but underwent, as in the third variant, four times additional deproteinization.

Activity of preparations was checked for six months.

Before implantation the injected material was tested for sterility. In the first replication when only penicillin (2,000 units/ml.) was applied, the plating on meat peptone agar revealed the presence of about 30,000 bacterial cells per ml. of incubated tumour homogenate. In subsequent replications, besides penicillin, streptomycin was used (500 units/ml.) and complete sterility obtained.

Weights of tumours in all the replications and variants of the experiment are given in Table 1. Inhibition of growth of tumours due to RNA was noted in all the replications. Variability of tumour weight in the control (Table 1) shows that the differences between the variants and the differences between the replications are probably due to a considerable extent to the fact that the condition of animals and/or of tumours used in one replication of the experiment differs from that used in another.

RNA and RNA additionally deproteinized cause a statistically significant decrease in the weight of the tumours as compared with the control. RNA depolymerization abolishes this effect. There is no reliable difference between the effects of RNA and RNA additionally depolymerized, whereas this difference exists between the data on RNA and RNA treated with RNase.

This evidence taken as a whole shows that RNA inhibits the growth of tumours under investigation and that antitumour activity of preparations is eliminated as a result of RNA enzymatic hydrolysis. The absence of statistically reliable differences between the effects of additionally deproteinized RNA and the RNA treated with RNase probably is due to the high variability of the results obtained. In this connexion attention should be paid to sharp differences of the data in some repetitions of the experiment. For example, while in the sixth replication the weight of tumours grown from the cells incubated with RNA hydrolysates even exceeded the weight of control tumours, in the third replication of this

variant a sharp repression of tumour growth was noted (Table 1).

Nevertheless, the total result is clear: RNA is an active component of preparations. Correspondingly their antitumour activity is not retained after RNase treatment with a subsequent additional deproteinization whereas the deproteinization itself does not inactivate preparations.

For some years certain antitumour agents have been found in the organs of normal animals<sup>13–16</sup>. If the tumour cells are incubated with them before implantation, the growth of tumour is inhibited. The chemical nature of these agents has yet to be investigated. The foregoing results show that the depolymerization of RNA inactivates the preparations used in the work recorded here. Hence, when before implantation the tumour cells were incubated with our preparations, the active component causing the growth inhibition of tumours was RNA, but not other substances extracted from normal tissues together with RNA (or contaminating the latter during isolation).

Our results do not support the suggestion that variations of the results obtained in the experiments on the effect of RNA depend solely on changes in the competence of recipient cells. The properties of the preparations used can serve as another source of these differences. At any rate until the preparative extraction of RNA fraction responsible for the registered effect (that is, for decrease in weight of the tumour as compared with the untreated control) is performed, this suggestion remains plausible. For example, the finding of the anti-tumour effect in all the replications of the experiment might depend on the fact that during the whole investigation with the one exception (replication 1) only the same RNA preparation was used.

There are some suggestions that the biological effect of RNA can be explained by its toxicity<sup>17,18</sup>. The experiments we performed on a series of tumour strains did not confirm this suggestion<sup>14,15</sup>. Moreover, special experiments have shown that the eleventh incubation of monolayer cultures of rat rhabdomyosarcoma with RNA from muscle tissues of the rat (RNA concentration 3.5–5 mg/ml.) does not decrease the proliferating activity of cells. Data on organospecificity of anti-tumour effect of RNA extracted from various tissues also contradict the suggestion concerning the toxicity of RNA preparations. Tumours are sensitive to the action of RNA isolated from homologous tissues and not susceptible or less susceptible to RNA separated from other tissues<sup>4,6</sup>.

It is probable that under the influence of RNA from the normal tissue homologous to the tumour the ability of autonomous growth of the latter is decreased<sup>4</sup>. If this is so, it would be of interest to examine the effect of RNA on the development of primary tumours: it is possible that at relatively earlier stages of autonomization the tumour cells would be rather sensitive to this agent.

The experiments which we performed with C<sub>3</sub>H mice in order to check this suggestion gave negative results. The development of hepatomas induced by orthoamino-

azotholuene was not retarded due to the action of the liver RNA repeatedly injected subcutaneously into the mice. This work is being continued.

To explain the anti-tumour effect of RNA it is not necessary to suggest that changes it induces are preserved for a long time. It is not improbable that a decrease over a short period in the ability of implanted cells to autonomous growth similar to short-time changes induced in bacteria by specific RNA from the outside<sup>18-21</sup> is sufficient for protective mechanisms of the animal to perform their function.

Another possibility is the participation of stable informational RNA in the process. The existence of such stable RNA in nuclear cells has been proved<sup>22</sup>. It is possible that they play the principal part in the vital activity of somatic cells of higher animals<sup>23</sup>.

Finally, we refer to the hypothesis according to which RNA from normal tissues causes in tumour cells epigenetic changes reducing their malignancy. Had such a result been obtained it could be compared with cell differentiation under the influence of specific RNA (the question concerning the possibility of such an influence at different stages of ontogenesis cannot be considered as finally settled<sup>24-26</sup>). It should be noted that we have not found redifferentiation phenomena in tumours grown from the cells incubated with RNA<sup>4</sup>. However, the morphological criterion is evidently not enough to determine the character of anti-tumour effect of RNA. In this connexion we should mention the results of two investigations of the action of specific RNAs<sup>6,27</sup> which show that the ability to synthesize proteins not normally produced by recipient cells may be retained over many cell generations.

The possibility of the appearance of epigenetic changes under the influence of RNA from the outside should be taken into consideration when comparing the biological effect of RNA and the transformation phenomenon conditioned by DNA. The great frequency of changes caused by specific RNA is the main difference available for the analysis at the present stage of knowledge<sup>20,21</sup>.

## ORGANOCHLORINE INSECTICIDE RESIDUES IN THE EGGS OF SEA BIRDS

By DR. N. W. MOORE

Monks Wood Experimental Station, Abbots Ripton, Huntingdon

AND

J. O'G. TATTON

Laboratory of the Government Chemist, London, S.E.1

IN 1963, organochlorine insecticide residues were found in the eggs of terns and other species feeding in British waters<sup>1,2</sup>. In 1964, the survey was extended to include specimens from 13 species collected at four sites. A preliminary examination of residues in the food of the birds at one site was also made. In all, 90 eggs were collected from Scolt Head, Norfolk; the Farne Islands, Northumberland; St. Abbs Head, Berwickshire (all on the North Sea coast); and from Great Saltee Island, County Wexford, which lies at the junction of St. George's Channel with the Atlantic. The eggs were from different clutches and were taken at random except at Scolt Head National Nature Reserve where only deserted eggs were taken. Thus, while strict comparisons cannot be made between the results of Scolt Head and the other sites, as the organochlorine pesticide residues in the Scolt Head eggs were found to be of the same order as those from the other sites they are probably not unrepresentative of the site. In all cases the residues were low and so were unlikely to have affected hatching success. Ten fish (1 sand eel *Ammodytes tobianus*, 1 pipe fish *Syngnathus*

sp., 2 plaice *Pleuronectes platessa*, and 6 gobies *Gobius minutus*) and 8 molluscs (2 mussels *Mytilus edulis* and 6 cockles *Cerastium edule*) were also collected from the feeding area of the sea bird colony at Scolt Head.

The specimens were analysed in the Laboratory of the Government Chemist using the extraction and clean-up method of de Faubert Maunder *et al.*<sup>3</sup> followed by gas-liquid chromatographic estimation of the pesticides using both silicone and 'Apiezon' columns in all cases. Confirmation of some of the results was possible by a paper chromatographic method.

The results from the sea bird eggs are summarized in Table 1. Dieldrin and *pp'*-DDE were detected in all the eggs. In addition, 70 specimens contained residues of *pp'*-DDT and/or its metabolite *pp'*-TDE; 47 contained traces of benzene hexachloride (BHC), usually the  $\beta$ -isomer and in no case exceeding 0.2 p.p.m.; 48 contained small amounts of heptachlor epoxide, none exceeding 0.2 p.p.m. These residues are included in the total residue figures given in Table 1. All of the molluscs and fish except for one cockle contained insecticide residues but in no case

T, trace (<0.1 p.p.m.). Inv., marine invertebrates (mainly Annelida, Crustacea) Mol., marine molluscs. Om., omnivorous. Species which feed partly on land or in fresh water are in square brackets.

did this exceed 0.1 p.p.m. Traces of pp'-DDT or its metabolites were present in 4 molluscs and all the fish and traces of dieldrin in 3 molluscs and 8 fish.

The following conclusions are drawn from the results: (a) Small amounts of organochlorine insecticides detected in marine life suggest that such residues may be widely distributed in British waters. (b) The total organochlorine insecticide residues found in the eggs of different sea birds are nearly all of the same order, most of them lying within the range of 0.4-3.5 p.p.m. (c) There are some indications that the eggs of birds which feed on large fish contain higher residues than those of species which feed on small fish or on invertebrates. (d) There is no evidence of an increase in contamination from 1963 to 1964, but some suggestion of a slight decrease. (e) Since there is little or no spraying of coastal waters with insecticides in Britain, the residues detected must derive either from the contamination of rivers or from aerial drift.

Analyses of freshwater molluscs, arthropods and fish in the fen rivers which drain into the Wash not far from Scot Head have indicated that traces of insecticides may be present in the molluscs and arthropods, with residues varying in the fish from a trace to a total of 19.5 p.p.m. in the case of the fat of a pike *Esox lucius*.

The existence and undesirability of environmental contamination by pesticides have been recognized by the Advisory Committee on Pesticides and Other Toxic Chemicals\*. Many uses of the more toxic organochlorine insecticides have been curtailed voluntarily in order to reduce this contamination; but in order to determine the effectiveness of these actions a measure of annual changes in residue levels in indicator organisms is required. The narrow limits within which the majority of the egg residues falls appear to be characteristic of marine species; residues for terrestrial species tend to vary within much wider limits<sup>1</sup>. This suggests that the eggs of sea birds may be useful indicator organisms for detecting general changes in environmental contamination by persistent pesticides. Since most sea birds range widely they would not be suitable indicators of local conditions.

We thank Mr. R. Chestney, Dr. R. S. Pitcher, Mr. G. R. Potts and Dr. D. A. Ratcliffe for collecting eggs.

## CHROMOSOME CHANGES IN HUMAN DIPLOID-CELL CULTURES INFECTED WITH *Mycoplasma*

By G. R. PATON, J. P. JACOBS and Dr. F. T. PERKINS

Division of Immunological Products Control, Medical Research Council Laboratories, Holly Hill, Hampstead, N.W.3

CONTAMINATION of mammalian cell cultures by *Mycoplasma* was reported for the first time by Robinson *et al.*<sup>1</sup>. Subsequent publications have shown that these agents occur frequently as contaminants in many animal cell cultures and that contaminated cells sometimes show morphological changes and alteration in their rate of growth<sup>2-4</sup>.

During routine chromosomal checks on a human diploid cell strain WI-38 which normally retains a diploid complement of chromosomes for at least forty passages under optimal conditions<sup>5</sup>, certain chromosomal aberrations were observed by us; polyploid counts and break frequencies were high, and occasional cells with fragmented chromosomes were seen. At about the time that these chromosomal abnormalities were detected, a decrease in the rate of cell growth occurred and the cultures were found to contain *Mycoplasma*. Since chromosomal aberrations associated with *Mycoplasma* infection

in normal cells have not previously been reported, it was decided to infect a strain of human diploid cells and to observe any changes which occurred. These findings are reported here.

Medium for cell growth consisted of Eagle's basal medium<sup>6</sup> (in Hanks's balanced salt solution) containing 8 per cent calf serum and 0.05 per cent sodium bicarbonate. No antibiotics were included in the medium.

The human diploid cell strain WI-38 developed from normal embryo lung by Hayflick at the Wistar Institute was serially passaged from cells frozen in liquid nitrogen. Cells were dispersed and propagated in 4-oz. bottles using the methods described by Hayflick and Moorhead<sup>5</sup>.

The *Mycoplasma orale* used was isolated from a continuous line of *Cercopithecus aethiops* (vervet) monkey-kidney cells (V34). The diploid cells which had been propagated for four consecutive passages in antibiotic-free medium were infected with a heavy inoculum immediately

after trypsinization while the cells were still in suspension. Both infected and control cultures were then trypsinized every three or four days and samples from both infected and control cultures were pooled and tested each week for the presence of *Mycoplasma* and microbial contaminants. The infected cultures and control cultures were handled in separate rooms.

Bottles containing many cells in mitosis were selected at intervals for chromosomal investigation, either 24 or 48 h after trypsinization. The cells were pretreated for 3 h with colcemid, and fixed in acetic alcohol. They were then spread on slides, lightly flamed, hydrolysed and stained in Giemsa (a modification of the method described by Moorhead and Nowell<sup>7</sup>). All intact metaphase cells were examined for heteroploidy, although it was not possible to count the chromosomes accurately in all cases; endore-duplicating cells were scored as polyploids. Well-spread metaphases were examined more closely and in all cases in which there was no ambiguity their chromosomes were counted and breaks scored. The term 'breaks' applies to a distinct break of the chromosome or chromatid but does not include secondary constrictions or unstained gaps. The figures in column 5 of Table 1 show the number of cells with one break or more and include fragmented cells (Fig. 1) which contain many fragments, chromatid exchanges and structural abnormalities.

Table 1. COMPARISON OF CHROMOSOME ABNORMALITIES OCCURRING IN NORMAL AND INFECTED CELLS

Passage	Days after infection	Polyploid cells		Cells with breaks		Fragmented cells	Structurally abnormal chromosomes
		+ <i>Mycoplasma</i>	Control	+ <i>Mycoplasma</i>	Control		
22	12	(31/323) 9.6%	(12/374) 3.2%	(18/151)* 11.9%	(5/107) 4.6%	1	3
28	38	(38/161)* 23.6%	(12/232) 5.2%	(20/78)* 25.6%	(1/147) 0.6%	12	1
31	42	(6/60) 10.0%	(10/185) 5.4%	(6/85) 7.0%	(3/76) 3.9%	2	1
32	47	(51/343)* 14.8%	(44/728) 6.0%	(13/122) 10.6%	(7/148) 4.7%	7	2

\* Indicates that the difference between infected and control cultures is significant at 5 per cent level.

Compared with *Mycoplasma*-free control cultures, cells experimentally infected with *Mycoplasma* showed noticeable cultural and cytopathic changes beginning by the second passage following infection. Progressive reduction in the rate of cell growth and a decrease in final cell population occurred together with cell elongation and increased cytoplasmic granularity. Tests to detect the presence of microbial agents were repeatedly negative, except for the consistent growth of *Mycoplasma* obtained from cell samples removed from infected cultures.

Fig. 1. Chromosomes from normal and infected WI-38 cells. Left, normal cell; right, infected cell (arrows indicate chromatid changes)

Table 2

Passage	Days after infection	Polyploid cells		Cells with breaks	
		+ <i>Mycoplasma</i>	Control	+ <i>Mycoplasma</i>	Control
28	5	(28/295)* 9.5%	(12/452) 2.7%	(27/185)* 14.6%	(10/149) 6.7%
	5	(22/332) 6.6%	(8/199) 4.0%	(41/277)* 14.8%	(9/130) 6.9%
29	6	(27/270)* 10.0%	(4/350) 1.1%	(16/79)* 20.3%	(4/85) 4.7%

\* Indicates that the difference between infected and control cultures is significant at 5 per cent level.

Chromosome examinations of the cells taken at four passage-levels are shown in Table 1. It is clear that the percentage of breaks and polyploidy was higher in the *Mycoplasma*-infected cells than in the controls. This difference tended to increase with time after infection, whereas the frequency of breaks and polyploid cells in the controls remained at a low level. The majority of infected cells had 46 chromosomes and, when analysed, the complement was of normal karyotype. Some of the infected cells were suspected of containing structurally abnormal chromosomes, but only unequivocal dicentric and translocation configurations are included in Table 1. With two exceptions fragmentation always occurred in heteroploid cells, the damage observed being so extreme that it was not possible to identify any of the remaining intact chromosomes many of which appeared structurally abnormal but were not included in column 8 of Table 1. Fig. 1 shows chromosomes in a fragmented cell, and a typical control cell.

Although Table 1 gives the results obtained during a long period of infection, we have also examined the chromosomes of WI-38 cells within six days following infection with *Mycoplasma* (Table 2). Three days after infection some of the cultures were growing more slowly than the controls and analysis of chromosome preparations made 5-6 days after infection suggested that the frequency of polyploidy and the number of breaks was greater than in the controls. Statistical analysis of the polyploid counts shows this difference to be significant in two cases out of three.

It is now recognized that *Mycoplasma* are common contaminants of cell cultures and may induce one or all of the following changes in contaminated cells: (1) reduction in growth rate, usually associated with a morphological change of the cells<sup>3,4</sup>; (2) reduction of arginine and glutamine in the growth medium<sup>3,5</sup>; (3) alteration of sensitivity of the cell cultures to viral infection<sup>6</sup>.

This communication shows that *Mycoplasma* may also change cell chromosomes, and therefore emphasizes the need for caution in interpreting experimental results

without adequately testing for the presence of *Mycoplasma*. Chromosome damage similar to that described here has been induced by viruses in cell cultures and in blood cultures<sup>8,10</sup>. Chromosomal abnormalities have also been reported in blood cultures and bone marrow from leukaemic patients<sup>11</sup>.

Hayflick identified Eaton agent as *Mycoplasma pneumoniae*, which causes primary atypical pneumonia and may be associated with other respiratory diseases in man<sup>12</sup>. *Mycoplasma* species have also been isolated from the synovial fluid of patients with rheumatoid arthritis<sup>13</sup> and from both human tumours and bone marrow from subjects with leukaemia<sup>14,15</sup>.

In most of these reports the evidence that *Mycoplasma* causes human disease is inconclusive; but the accumulated data strongly suggest that an association exists. Our evidence that chromosomal aberrations occur in normal human cells after infection with *Mycoplasma* is of particular interest, but further investigations are needed to

establish the full significance of our observations. These preliminary findings, however, add support to the opinion that *Mycoplasma* may be involved in the aetiology of human disease.

We thank Dr. M. Westwood for supplying and identifying the *Mycoplasma* used in the major part of this work, and Mrs. I. Teahime for help in microscopy.

## CONTRALATERAL EFFECTS OF SODIUM AND POTASSIUM ON THE ELECTRICAL POTENTIAL IN FROG SKIN AND TOAD BLADDER

By PROF. FRED M. SNELL and TUSHAR K. CHOWDHURY

Department of Biophysics, State University of New York at Buffalo

THE effects of  $\text{Na}^+$  and  $\text{K}^+$  bathing the outside and inside surface of frog skin and the corresponding mucosal and serosal surface of toad bladder (hereafter referred to as outside and inside) on the transmembrane electrical potential are well recognized. Under conditions in which the anion permeability is negligible, that is, by using  $\text{SO}_4^{2-}$  as the predominant anion, Koefoed-Johnsen and Ussing<sup>1</sup> have stated that the total transmembrane potential is composed of two parts and described by the relation:

$$\psi_i - \psi_o = \Delta\psi = \frac{RT}{F} \left[ \ln \frac{[\text{Na}^+]_o}{[\text{Na}^+]_i} + \ln \frac{[\text{K}^+]_i}{[\text{K}^+]_o} \right] \quad (1)$$

where the subscripts, *o* and *i*, refer to the outside (mucosal) surface and inside (serosal) surface, respectively, and the subscript, *c*, refers to the cell cytoplasm. *R*, *T* and *F* are the gas constant, the absolute temperature and Faraday respectively, and the bracketed chemical symbols denote the concentration of the respective ions. Other investigators have confirmed this to varying degrees, although disagreement has arisen in two regards. In the case of frog skin derived from a variety of species, as well as toad bladders<sup>2</sup>, the magnitude of the slopes,  $\partial\Delta\psi/\partial \log [\text{Na}^+]_o$  (log refers to base 10) and  $\partial\Delta\psi/\partial \log [\text{K}^+]_i$ , is, more often than not, less than the value of  $2.3 RT/F$  as given in equation (1), that is, 59 mV per log unit at 25° C. Furthermore, these slopes, more often than not, are not constant over the range of experimental observation. Both of these kinds of findings have been 'explained' in terms of passive shunting, that is, leakiness of the bounding membrane to other ions. For example, in a rather extensive study, Lindley and Hoshiko<sup>3</sup> have interpreted their results, with some success, by applying the constant field equation of Goldman<sup>4</sup>.

No reports have appeared on the contralateral transmembrane effects of one of these ionic concentrations,  $[\text{Na}^+]_o$  or  $[\text{K}^+]_i$ , on the functional dependence of the potential on the other, that is,  $[\text{K}^+]_i$  or  $[\text{Na}^+]_o$ . For example, the question may be asked: does  $[\text{Na}^+]_o$  have any effect on the electrical potential as a function of  $[\text{K}^+]_i$ ,  $\Delta\psi([\text{K}^+]_i)$ , or does  $[\text{K}^+]_i$  have an influence on the function,  $\Delta\psi([\text{Na}^+]_o)$ ? We have carried out a brief but systematic investigation of such contralateral effects in both isolated frog skin (*Rana pipiens*) and toad bladder (*Bufo marinus*). The results would appear to have important implications on any interpretation of the origin of the transmembrane potential and reflect on the validity of the interpretation ascribed by the Koefoed-Johnsen and Ussing model<sup>1</sup>.

Either the abdominal skin of frog or the urinary bladder of toad was isolated in the usual manner. Within 1-4 h after isolation, it was mounted in a two-chamber cell

providing 3.8 cm<sup>2</sup> of area and so designed that the solutions bathing the surfaces could be conveniently changed, thereby to alter the ionic compositions. All experiments were carried out during the period April-November and were performed at room temperature of about  $25 \pm 1^\circ \text{C}$ . Both the open-circuit total transmembrane potential and the short-circuit current were measured<sup>5</sup>. The ionic compositions in the bathing solution were varied in a systematic manner. At a given  $\text{Na}^+$  concentration in the 'sulphate' Ringers' solution bathing the external surface,  $[\text{Na}^+]_o$ , the  $\text{K}^+$  concentration in the solution bathing the internal surface,  $[\text{K}^+]_i$ , was incrementally changed substituting  $\text{Na}^+$  with  $\text{K}^+$ , approximately doubling  $[\text{K}^+]_i$  for each successive change to cover the range 2.5-117.5 mM. (The sodium 'sulphate' Ringer's solution used was composed as follows:  $\text{Na}_2\text{SO}_4 = 57.5 \text{ mM}$ ,  $\text{CaSO}_4 = 1.5 \text{ mM}$ ,  $\text{K}^+ (\text{KH}_2\text{PO}_4 - \text{K}_2\text{HPO}_4) = 2.5 \text{ mM}$ , sucrose 60 mM for frog Ringer's solution, glucose 20 mM for toad Ringer's solution,  $\text{pH} = 7.4 \pm 0.1$ .) After each change, sufficient time was allowed for the potential and short-circuit current to become relatively stable. Following the highest  $[\text{K}^+]_i$  examined, sodium sulphate Ringer's solution containing 2.5 mM  $\text{K}^+$  was again applied to the surface and  $[\text{Na}^+]_o$  was then altered by substituting choline or  $\text{K}^+$  for  $\text{Na}^+$ . (Choline sulphate was prepared by neutralizing choline bicarbonate (Matheson 40 per cent aqueous solution) with sulphuric acid.) The changes in  $[\text{K}^+]_i$  were then repeated. In this manner, the total transmembrane potential was examined as a function of both  $[\text{Na}^+]_o$  and  $[\text{K}^+]_i$ . In some experiments, the procedure was to alter  $[\text{Na}^+]_o$  sequentially at given values of  $[\text{K}^+]_i$  to obviate bias in any irreversible effects of drifts in preparation behaviour. The results show clearly in both frog skin and toad bladder that as the  $\text{Na}^+$  concentration bathing the outside surface,  $[\text{Na}^+]_o$ , is decreased, the magnitude of the slope,  $\partial\Delta\psi/\partial \log [\text{K}^+]_i$ , decreases. Whereas this slope may be as much as -50 mV per log unit at 115 mM  $[\text{Na}^+]_o$ , it is often not more than -15 mV per log unit at 1 mM  $[\text{Na}^+]_o$ . In a like manner, the results show that as  $[\text{K}^+]_i$  is increased, the slope,  $\partial\Delta\psi/\partial \log [\text{Na}^+]_o$ , decreases. Results from a representative experiment from a total of ten are plotted in Fig. 1.

From the short-circuit current measurements, patterns analogous to those found for the open-circuit transmembrane potential emerge. Data from the same experiment illustrated in Fig. 1 are plotted in Fig. 2.

The electrical resistance, taken as  $\Delta\psi/I$ , where *I* is the short-circuit current, decreases with both increasing  $[\text{Na}^+]_o$  and increasing  $[\text{K}^+]_i$ .

According to the Koefoed-Johnsen and Ussing<sup>1</sup> model, the only means whereby these contralateral transmembrane effects could be realized would be through changes

in  $[Na^+]_o$  and  $[K^+]_o$  (equation 1) accompanying the changes made in the bathing solution. However, as MacRobbie and Ussing<sup>4</sup> have shown, such changes are not expected with the use of  $SO_4^{2-}$  Ringer's solutions since anion permeability is so small. Indeed, using  $^{35}SO_4^{2-}$ , we were unable to detect measurable transmembrane flux in 30-min periods<sup>5</sup>. It is not inconceivable that there may be cytoplasmic changes in composition, changes which in effect amount to exchanges of  $Na^+$  for  $K^+$  and vice versa, presumably with some preservation of the total osmotic concentration. These changes, it may be argued, would lead to slopes less than that given by equation (1), that is, 59 mV per log unit, but the reduction in magnitude would be expected to be greatest at high  $[Na^+]_o$  and low  $[K^+]_o$ , the reverse of that observed. Essig and Leaf<sup>7</sup> have interpreted the effect of bathing the serosal surface with  $K^+$  free Ringer's solutions, an effect characterized by a marked reduction in active sodium transport, as one attributed to an increased resistance of the mucosal bounding membrane. Presumably this increase in  $[K^+]_o$  should decrease the resistance of this bounding membrane and lead to an increase in active sodium transport, an effect again opposite to that observed (Fig. 2).

Fig. 1. Data from a representative experiment showing the effect of varying  $[K^+]_o$  on the potential,  $\Delta\psi$ , across frog skin at different values of  $[Na^+]_o$ . The numbers refer to the sequence of  $[Na^+]_o$  changes: 1,  $[Na^+]_o = 115$  mM; 2,  $[Na^+]_o = 30$  mM; 3,  $[Na^+]_o = 6$  mM; 4,  $[Na^+]_o < 1$  mM.

Fig. 2. Data from the same experiment as shown in Fig. 1 showing the effect of varying  $[K^+]_o$  on the short-circuit current,  $I$ , at different values of  $[Na^+]_o$ . The area of the skin was about 3.8 cm<sup>2</sup>.

In view of our recent findings from microelectrode investigations, showing that the slopes  $\partial\Delta\psi_m/\partial\log[Na^+]_o$  and  $\partial\Delta\psi_m/\partial\log[K^+]_o$  ( $\psi_m$  being the potential measured by the microelectrode) are continuous and are linear functions of distance in that tissue region manifesting the total electrical potential<sup>8</sup>, we are more inclined to attribute the contralateral effects of  $Na^+$  and  $K^+$  on the potential as mediated by their primary effects on the sodium transport system. In this respect, therefore, one must conclude that at concentrations in the range 0–2.5 mM,  $K^+$  bathing the inside (serosal) surface acts as an activator of the sodium ion transport system, but as the concentration is increased above this level,  $K^+$  serves to inhibit the system in a manner reminiscent of non-competitive inhibition of enzymes. Mechanisms at this point must remain a matter of conjecture, but it is not inconceivable that the  $Na^+$  and  $K^+$  sensitive ATPase<sup>9</sup> may be involved.

## CONTROL OF GLYCOLYSIS IN WASHED SUSPENSIONS OF *Streptococcus faecalis*

By DR. W. W. FORREST and DR. D. J. WALKER

C.S.I.R.O. Division of Biochemistry and General Nutrition, University of Adelaide, South Australia

IT has been proposed that control of the rate of anaerobic glycolysis is mediated by intracellular orthophosphate or feedback mechanisms involving adenosine triphosphate (ATP)<sup>1</sup> and adenosine diphosphate (ADP)<sup>2</sup>. It is postulated that, if an organism increases its energy requirements, the rate of hydrolysis of ATP increases; this causes the feedback system to operate to oppose any change in the level of ATP by increasing the rate of glycolysis so that the rate of production of ATP is correspondingly increased to balance the changed conditions. This argument would require that an organism should exhibit a fairly constant pool of ATP or ADP; but measurements

of the sizes of these pools have been rather inconclusive<sup>3</sup>, and Commoner<sup>4</sup> proposes that direct feedback control is inoperative in non-growing organisms.

It has apparently not been suggested that adenosine monophosphate (AMP) is involved in regulation of glycolysis; however, the recent suggestion that this compound is responsible for feedback control of gluconeogenesis<sup>5</sup>, makes it necessary to consider AMP also as a possible intermediate in control of glycolysis.

Measurements of rates of glycolysis and the level of the ATP pool in non-growing suspensions of cells of the facultative anaerobe, *Streptococcus faecalis*, suggest that there is

no feedback control of glycolysis in a washed suspension and that control is exerted indirectly through the endogenous metabolism of the organisms. ATP is involved in regulation, but the ATP pool concerned is not that directly participating in glycolysis.

In a washed suspension of cells suspended in a phosphate buffer the intracellular level of inorganic phosphate will be high and constant<sup>1</sup>. In addition, the cells can at most maintain the *status quo* since no extracellular materials for synthesis are present; accordingly the total concentrations of the adenine nucleotides will be constant, and the time-scale in the experiments to be described is long enough to permit the assumption that equilibrium between the concentrations of the nucleotides will be maintained. Making similar assumptions to these, Krebs<sup>2</sup> has calculated that under physiological conditions a small change in the concentration of ATP reflects larger changes in the other nucleotides. The relative changes are ATP1:ADP2:AMP15, so that examination of the ATP pool alone should indicate whether regulatory mechanisms exist in non-growing suspensions.

In experiments to examine the level of the ATP pool, *Streptococcus faecalis* (A.T.C.C. 4083) was grown on complex medium containing 2 per cent each of sodium citrate, dried yeast extract, peptone and glucose. Washed suspensions were prepared from cells 17 h after inoculation by washing twice in de-aerated 0.2 M phosphate buffer, pH 6.2, and suspending in the same buffer under a gas phase of nitrogen at a cell density of about 1 mg/ml. Pool-levels were measured by a modification<sup>3</sup> of the method of Strange *et al.*<sup>4</sup>, using 0.3 M sulphuric acid to extract ATP from cells and a recording photometer to measure the bioluminescence produced in the luciferin-luciferase assay method.

In a washed suspension of cells carrying on glycolysis, the kinetics of glycolysis are accurately of zero order and a constant rate of glycolysis has been observed for several hours when large quantities of glucose are added to a suspension<sup>5</sup>. If control were exerted through the nucleopools, a constant level should be observed in the ATP pool; but in fact the level of the ATP pool during glycolysis may increase to ten times the level found in a cell suspension in the absence of energy source (Fig. 1). The process operating is the combination of a constant rate of increase in pool level concomitant with a constant rate of generation of ATP from glycolysis, opposed by an exponential decay. These processes eventually balance, so that the pool-level asymptotes to an upper limit. When all the added glucose has been metabolized the decay process alone operates. Calculation of the rate of generation of ATP from glycolysis, compared with the measured level of ATP in the pool, indicates that the turnover time of the

Fig. 1. The ATP pool in *S. faecalis* during glycolysis. Cells grown on 2 per cent complex medium, washed and suspended in 0.2 M phosphate buffer, pH 6.2, under nitrogen. Cell density 1.48 mg/ml. Fig. 2. The rate of glycolysis of cells with and without added amino-acids. Cells aged as in the experiment of Fig. 1, then resuspended in 0.01 M phosphate buffer, and rate of hydrogen ion production measured by titration with 0.1 N NaOH. 6.4 mg cells. Substrate glucose 4 mg/ml. At arrow 0.5 mg/ml casamino acids were added.

ATP in the pool is about 5 sec; this is short compared with the half-time of the decay process.

Cells of *S. faecalis* lacking reserve materials for endogenous metabolism can incorporate amino-acids into cellular material at a rapid rate<sup>6</sup>. In the experiment shown in Fig. 1 the cell suspension was aged for 150 min before the addition of substrate so that endogenous reserves<sup>10</sup> were depleted but not exhausted, then glucose alone was added to one aliquot of cells and glucose plus amino-acids from casein hydrolysate to the other. The synthetic reactions occurring during incorporation of amino-acids deplete the ATP pool so that the rise in the level of the pool is much less and the asymptotic limiting value is only about half that found with glucose alone. However, the rate of glycolysis is not significantly affected by the addition of casamino-acids to the suspension (Fig. 2).

These findings are in direct contradiction to the hypothesis of feedback control. A constant rate of glycolysis is accompanied by a very large change in the level of the ATP pool and presumably also the ADP and AMP levels, yet an increased demand for energy to perform synthetic reactions, though it lowers the ATP pool level drastically, does not affect the rate of glycolysis. The ATP pool appears to behave as a dependent variable rather than one exercising control.

When *S. faecalis* is grown on complex media with excess energy source, as in these experiments, reserve materials are accumulated; starved washed suspensions of such cells in phosphate buffer exhibit a large endogenous metabolism which continues for several hours<sup>10</sup>, and the glycolytic activity, determined by withdrawing a sample of cells from the suspension, adding glucose to this sample and titrating the hydrogen ion produced at pH 6.0, is constant over the whole of this period. The glycolytic activity found in these measurements has a characteristic value of 0.07  $\mu$ moles of glucose per min per mg dry-weight of cells at 37° C; it is unaffected by the environmental factors which influence endogenous metabolism<sup>11,12</sup>.

Fig. 3 shows that the level of the ATP pool in a starved suspension is constant for the period during which endogenous metabolism and constant glycolytic activity are observed. The pool-level is unaffected by the addition of thioglycollate, which markedly affects the rate of endogenous metabolism<sup>13</sup>. Similarly, it has been found that change in the concentration of cells in the suspension, which also strongly affects endogenous metabolism, has no significant effect on the pool level.

Fig. 2. The ATP pool in starved, washed suspensions. Cells with endogenous reserves, grown and suspended in phosphate buffer as in the experiment of Fig. 1. Cell density 0.69 mg/ml. ○, No thioglycollate; ●, 0.05 per cent sodium thioglycollate added; △, cells without endogenous reserves, grown on complex medium containing 0.1 per cent glucose, washed and suspended as in previous experiments. Cell density 0.73 mg/ml; □, cells with endogenous reserves, suspended in 0.2 M citrate buffer pH 6.2 under nitrogen. Cell density 1.23 mg/ml.

In contrast to this behaviour, suspensions in phosphate buffer prepared from cells grown on complex medium with the concentration of glucose reduced to 0.1 per cent so that the growth was limited by source of energy, have no detectable endogenous metabolism. The ATP pool has no period with a constant level. The glycolytic activity of the suspension is not maintained at the constant level characteristic of cells carrying on endogenous metabolism, but is initially higher than this and falls rapidly, losing about 10 per cent of the initial activity per hour.

It is found that phosphate buffer concentrations between 0.01 M and 0.2 M have no effect on glycolytic activity. However, incubation of washed suspensions in citrate buffer of cells grown with excess energy source abolishes the period of constant glycolytic activity<sup>8</sup> and the ATP pool stabilizes at a low level because of the depletion of intracellular phosphate<sup>1</sup>, even though, in this case, endogenous reserve materials are present.

The experiments suggest that glycolysis in washed suspensions of *S. faecalis* is not controlled by direct feedback. During the period of endogenous metabolism the glycolytic activity remains constant regardless of whether the suspension is incubated with or without glucose, so

that no feedback loop depending on glucose can operate. It seems that the cells have a fixed capacity for glycolysis which is not modified by their environment (provided phosphate is present) or their energy requirements. This behaviour can be explained, without postulating feedback, by normal kinetic mechanisms. We have not observed a glycolytic activity which is stable with time, lower than that found in such a washed suspension; cells which have exhausted their endogenous reserves and lost glycolytic activity after prolonged incubation have a glycolytic activity which continually decreases with time<sup>10</sup> in the absence of glucose, but when energy source is added they tend to restore their rate of glycolysis<sup>9</sup> towards the level characteristic of cells possessing endogenous metabolism.

For a fixed rate of glycolysis to be operative, it is necessary that a sufficient quantity of active enzymes should be present. Energy appears necessary to maintain these, and the supply of this energy seems to be one function of the endogenous metabolism. If there is no endogenous metabolism, or a sufficient ATP pool to couple the energy from this process to maintenance reactions is not available, no period of constant glycolytic activity is found, so that ATP seems to be involved in regulation of glycolysis in washed suspensions only in this limited sense.

The rate of endogenous metabolism and presumably of generation of ATP increases under conditions of environmental stress<sup>10</sup>. However, the ATP pool is unaffected by the change in endogenous metabolism, suggesting that this metabolism is regulated to the energy requirements of the organisms. The rate of generation of ATP by endogenous reactions gives rise to a pool-level small compared with the pool-level measured during glycolysis, yet it appears sufficient to allow the organisms to maintain themselves; glycolysis in washed suspensions may therefore generate ATP greatly in excess of the requirements of the cells, and the control systems of the organisms apparently cannot 'shut down' sufficiently to prevent this happening.

## CONTINENTAL DRIFT

### Continental Drift and the Age of Angiosperm Genera

THE decades of dispute and indecision over the hypothesis of continental drift seem to be drawing to a close. Modern techniques such as rock magnetism measurement, investigations of ancient climates and palaeowinds, and also the computer investigations of continental outlines reported by Sir Edward Bullard<sup>1</sup>, all point to the fact that continental drift has been and probably still is occurring. A further major factor in the discussion may be the time at which drift began, and when the present continental areas were delimited. This question is of great significance to plant geography and evolution, where the problems of plant distribution in disjunct areas frequently suggest a correlation with continental drift or former intercontinental land connexions.

Such disjunctions in areas of distribution over the globe are perhaps most marked in the southern hemisphere, where the distances between continents are very great.

Several angiosperm genera can be cited, a classic example being the cotton genus *Gossypium*. Here, taxonomic sections or groups of sections have been shown to possess different genomes, most of which are confined to different continental masses. Thus the *D* genome (Sections *Ericoxyla*, *Klotzschiana* and *Thurberana*) is confined to the American continent and the *O* genome (*Sturtiana*) to Australia. Even though the *B* and *H* genomes are found in Africa it is possible that one of them might have migrated into that continent from India as suggested by Hutchinson, Silow and Stephens<sup>2</sup>. These authors have postulated Cretaceous fragmentation of a former super-continent in order to explain present-day distribution of the genus.

In the grass genus *Bromus*, distinct sections based on morphological, cytological, genetic, serological and biochemical criteria are found in the various southern continents. The very distinct section *Ceratochloa* occurs in South America, as does the peculiar *Neobromus* group. *Ceratochloa* in North America probably developed by

hybridization of South American species<sup>8</sup> when they migrated north over the Central American link in the Pliocene or later. The Section *Bromopsis*, although mainly North American and Eurasian, occurs also in Africa. *Bromus* distribution therefore suggests that the early primitive forms were widespread over a large land mass, but produced the present well-marked sections owing to geographical isolation caused by continental fragmentation and drift.

Although the genus *Solanum* is pantropical, of the six sub-genera recognized by Seithe<sup>4</sup>, four are mono-continental. Thus the sub-genera *Lycopersicon* and *Bassovia* are confined to South America, *Archaeosolanum* to Australia and New Zealand, and *Lyciosolanum* to Africa. The two other sub-genera, *Solanum* and *Stellatipilum*, are widespread. These latter have been divided by Seithe into 42 sections and sub-sections, and 32 of these (some 75 per cent) are also mono-continental. Many of the others may well owe their wide distribution to the 'woody tendencies' exhibited by certain species, which have enabled them to spread rapidly as adventives in more recent times.

To quite a large extent, therefore, the taxonomic groupings within the genus *Solanum* accord with the geographical separation of the three southern continents, South America, Africa and Australia.

Many other examples might be quoted, for example, leafy Hepaticae<sup>9,10</sup>, and marine Copepoda<sup>7</sup>, where the facts of distribution are most convincingly explained by continental drift.

Continental drift seems now to be a more acceptable theory than the alternative hypothesis of land bridges, since Heezen<sup>8</sup> states that the petrography of ocean floors is markedly different from that of continental areas. This clearly reduces the likelihood of the sea-bed ever having been a land area, except in a very few cases, for example, near the coast of South Africa, where submergence of continental blocks could have taken place. Another possible explanation of disjunct distributions of organisms is by chance long-distance dispersal. If this phenomenon were at all important we should expect the vegetation cover of the world to be much more uniform than it is. Furthermore the very high endemism in isolated oceanic islands seems to show that long-distance dispersal is a very inefficient method of spread.

The major objection to continental drift as an explanation of modern plant distribution has been that it occurred too early, before modern genera were in existence. However, although the break-up of the ancient continent of Gondwanaland has often been placed at the end of the Triassic, Lester King<sup>9</sup> quotes evidence that it started in the mid-Jurassic (140 million years ago), and not until mid-Cretaceous (about 90 million years ago) were the present outlines of the continents defined. Thus King regards drift as a primarily Jurassic to mid-Cretaceous occurrence. His basic evidence for the existence of the present continents in past times is the presence of continuous and uninterrupted sequences of marine deposits on modern continental margins dating from mid-Jurassic at the earliest. This dating of continental origin and drift is in the period when the angiosperms are thought to have been actively evolving, and it is likely that the angiosperms are older than is at present realized<sup>10</sup>.

On the basis of palaeomagnetic data, Creer<sup>11,12</sup> thinks that the beginning of the split occurred in Permo-Triassic times, some 200 million years ago. The polar wandering curves for South America, Africa and Australia begin to diverge at the Permo-Triassic point, although the indications are that Antarctica did not separate from South Africa until possibly Jurassic times. Apart from this, the separation of the various parts of Gondwanaland is thought to have been complete by the end of the Triassic, some 180 million years ago. Nevertheless, it is thought that drift continued up to the Tertiary. Considering these same data, again in the form of polar wandering curves, Khan, on the other hand (private communication), believes that

drift could have begun in the mid-Mesozoic and that the significant splitting and drifting of parts of Gondwanaland took place during the Cretaceous.

From the above-mentioned geological data we must conclude that genera such as *Gossypium*, *Bromus* and *Solanum* were already in existence by at least early Cretaceous (about 100–120 million years ago), since by that period, according to King<sup>9</sup> and many other geologists, the present southern continents had drifted apart. On Creer's rock magnetism data the formation of these genera must be considered to be even more ancient, and must date from Permo-Triassic times, at least 200 million years ago. If we take the more conservative estimate of King and others this still means that at least some of the angiosperm genera were in existence about 100 million years ago, and we are therefore forced to the conclusion that the families to which they belong must be older still. We naturally assume that the 'genus' when first formed would not have been recognizable as such but might rather have been a widespread—and perhaps highly variable—series of forms to which, if we had been able to see it then, we might have given the status of species.

One other point of interest to biologists emerges from these recent geological investigations on continental drift. This concerns the very rapid advance of the flowering plants in Cretaceous times, a fact which considerably excited the attention of Charles Darwin. To quote Darwin himself<sup>13</sup>: "The rapid advance, as far as we can judge, of all the higher plants within recent geological times is an abominable mystery". With what seems to us nowadays to be prophetic judgment, Darwin also states<sup>14</sup>: "I have been so astonished at the apparently sudden coming in of the higher phanerogams, that I have sometimes fancied that development might have slowly gone on for an immense period in some isolated continent or large island, perhaps near the South Pole". This thought has also occurred to various botanists since Darwin's time. For example, Camp<sup>15</sup> voiced the opinion that "the divergencies of the basic generalized familial groups had been accomplished on this southern land mass (i.e. Gondwanaland) certainly by the mid-Mesozoic". The same view was held by Seward<sup>16</sup> and by Hemsley Thomas<sup>17</sup>.

On the other hand, Stebbins<sup>18</sup> thinks that the apparently rapid evolution of the angiosperms could be accounted for by assuming that their origin was not much earlier, geologically speaking, than their first appearance in the fossil record, and that during this period they were undergoing a burst of particularly rapid evolution. Takhtajan<sup>19</sup> considered that the geographical changes associated with the break-up of Gondwanaland brought about a rapid spread of the angiosperms at the expense of other plant groups because of their "high evolutionary plasticity expressed by their extraordinary diversity" (English translation, p. 13).

While this view of the rapid extension of angiosperms in mid-Cretaceous times sounds very plausible, another possible explanation for their sudden appearance should be considered. The distributional data presented here indicate that angiosperm families must have been in existence, possibly as small populations only, at least by Jurassic times, and that the group as a whole may have originated even further back, in Carboniferous or Permian, in the southern land mass of Gondwanaland. Their virtual absence in pre-Cretaceous times from the better-studied rocks of the northern hemisphere may then be accounted for by assuming that the evolution of the earlier families and genera took place in Gondwanaland. According to Takhtajan<sup>19</sup> no undoubted angiosperm fossils other than spores are to be seen in the Jurassic; impressions of angiosperm leaves appear in the Lower Cretaceous (Neocomian) (though there is some doubt as to their authenticity); undoubted dicotyledonous leaves are seen in the second half of the Lower Cretaceous (Aptian and Albian), but it is not until the Upper Cretaceous (some 90 million years ago) that they become really abundant. So far as we can see,

all this information is obtained from northern hemisphere rocks.

These data could readily be explained by postulating an exclusively Gondwanaland origin for angiosperms, which were unable to colonize the northern land masses until the fragments of the southern super-continent had drifted like rafts, with the flowering plants growing on them, into the vicinity of Laurasia. According to King<sup>11</sup> (and private communication), so far as north Africa and south Europe are concerned, this collision "would seem to have taken place about the mid-Cretaceous (pre-Gosau) movements of the Alpine belt. For India the same Tethyan geosyncline was filled up by the late Cretaceous, by which time India would appear to be united with Asia and great mountains had been formed". King goes on to state, however, that "These dates are provisional only".

This palaeogeographical evidence of a mid-to-late-Cretaceous union of some of the southern land-masses with Europe and Asia accords very well with the generally accepted period in which the really abundant angiosperm fossils appeared in these latter regions. Before this, there is only scanty evidence of leaf impressions (lower Cretaceous) while even earlier (Jurassic) only spores have been observed. This would fit well with the assumption that in Jurassic times the light, wind-borne spores floated northwards from Gondwanaland over a gap that the heavier seeds themselves could not bridge. As the gap narrowed, a few genera, perhaps with lighter seeds or more efficient methods of dispersal, colonized the northern land mass, forming a vanguard to the main colonizers which followed in enormous quantities, once the land connexion had been firmly established in mid-Cretaceous. Axelrod<sup>12</sup> quotes evidence that the advancing angiosperms spread northwards from tropical regions once part of Gondwanaland, based on the fact that fossil angiosperm material occurs in lower strata at lower latitudes. His evidence for southward migration is very scanty.

This hypothesis of the advance of the angiosperms presupposes that the group was quite numerous in Gondwanaland, or at least must have been widely dispersed there in Mesozoic times. Angiosperms were certainly not numerous in the Jurassic of Yorkshire in one of the best known sites in the northern hemisphere, according to Harris<sup>13</sup>, who states: "I would say that the Jurassic flora of Yorkshire which has been studied scientifically for about 140 years must have had about as much time spent on it, in relation to its size, as any other flora on earth... and no one has found a real angiosperm in it". Although no undoubted angiosperm fossils have yet been found in the Palaeozoic to Mesozoic floras of the southern hemisphere, it could hardly be claimed that as much work had been done on them as on the Jurassic flora of Yorkshire. Plumstead<sup>14</sup> has contributed a great deal of knowledge to the palaeobotany of the southern hemisphere and especially of the *Glossopteris* flora. Although she cites and discusses the work of other investigators in the field, it becomes clear that the hoped-for abundance of angiosperms still cannot be verified, unless, as King (private communication) suggests, the *Glossopteris* flora could itself be considered as the earliest angiosperms. This seems rather unlikely, at the present state of our knowledge.

The apparent absence of fossil angiosperms in the southern hemisphere might be explained partly by assuming that the flowering plants occurred as small, rather isolated populations and that although some fossil material may exist it has not yet been discovered because of its relative scarcity. It could also be explained by assuming that the ecological distribution of the early angiosperms was such that they largely escaped preservation. Axelrod<sup>12</sup> and Heslop-Harrison (private communication) have discussed the possibility that the Gondwanaland flowering plants might well have exploited drier, non-fossilizing habitats (possibly montane) situated well away from the competition of the humid *Glossopteris* flora.

The facts of distribution of the genera quoted at the beginning of this paper, *Bromus*, *Gossypium* and *Solanum*, cannot readily be explained unless we assume that they were already present in Gondwanaland at least by early Cretaceous times, almost certainly during the Jurassic, and possibly even earlier. We therefore suggest that a re-examination of existing material and a renewed search in other southern continental areas should be made, especially in deposits that are known to have been separated from the delta and swamp conditions inhabited by the Glossopterids, either along the margins of these regions or in what are believed to have been upland, montane or semi-desert areas. Harris<sup>13</sup> states: "We want early angiosperms urgently, almost as a thirsty man needs water". We agree, and therefore suggest that renewed efforts should be made to examine Mesozoic rocks of the former land mass of Gondwanaland for such fossils, since it is there that the distributional evidence of present-day plants indicates that they should be found.

We may summarize our conclusions as follows:

(1) Distributional evidence of living plants indicates that angiosperms were almost certainly present on the super-continent of Gondwanaland in Mesozoic times, if not before.

(2) Representatives of some modern genera of flowering plants were in existence by at least early Cretaceous times (100-120 million years ago).

(3) From the present lack of evidence of abundant flowering plant remains in the southern continents one must assume that they were rare in those areas until mid-Cretaceous or were exploiting drier and therefore largely non-fossilizing habitats (possibly montane).

(4) A possible explanation for the apparently sudden appearance of flowering plants in the northern hemisphere is that they evolved in Gondwanaland and were able to migrate from it only after one or more of its fragments had drifted northward and come into contact with the northern land masses of Europe, Asia and North America.

(5) A more intensive search for fossil angiosperms should be made among Mesozoic deposits from the southern hemisphere (including parts of former Gondwanaland now in the northern hemisphere) and especially in deposits, if any can be detected, that lie marginally to, or completely away from, the main lowland fossil beds.

We thank Dr. R. J. Adie, Dr. K. M. Creer, Prof. J. Heslop-Harrison, Dr. A. Khan, Prof. Lester King and Dr. I. Strachan for their advice.

## Palaeomagnetism and the Time of the Onset of Continental Drift

My conclusion that Gondwanaland started to break up in the Permo-Triassic<sup>1</sup> should be regarded as an early limit. It depends partly on palaeomagnetic work on the vast Mesozoic basalt and diabase formations of the Gondwanic continents<sup>2-4</sup>. The procedure was to compute mean palaeomagnetic directions for each continent, namely, South America, Africa, Australia, Antarctica, and India. These directions correspond to the mean age of each formation, and, in the absence of evidence to the contrary, these ages were taken to be the same. On this basis it was concluded that the palaeolatitudes and palaeomeridian directions were inconsistent both with the present arrangement of the continents and also with their arrangement as adjacent parts of Gondwanaland<sup>5</sup>: the palaeomagnetic data were consistent with an intermediate arrangement of continents. The assumption that the mean age of igneous activity was the same in all the Gondwanic continents was a reasonable one to make initially. However, it is not adequate for more precise work.

Potassium argon ages have now been determined for the Serra Geral formation (South America) and are grouped round 140 m.y. and 120 m.y.<sup>6,7</sup>. Stormberg lavas (South Africa) have been dated at 190 m.y. and 184 m.y.<sup>8</sup>. Tasmanian dolerites have been dated at 170 m.y.<sup>11</sup> and Ferrar dolerites (Antarctica) at 163 and 147 m.y.<sup>12</sup>. Hence the ages of the rocks sampled for palaeomagnetic

investigations in the Gondwanic continents could possibly differ by some tens of millions of years. If continental drift or polar wandering were rapid in those times, the conclusions drawn from the original surveys may have to be modified.

It is not possible to divide palaeomagnetic data at present available into radiogenically dated sub-groups. However, more complete surveys are now being carried out in South America and in Africa, and every lava flow and dyke used will have to be dated radiogenically.

In due course it should be possible to answer with more assurance the question of whether the onset of drift was associated with the first outpourings of lava 190 m.y. ago, whether it started rather earlier as I had concluded, or later (preceding communication).

## DEPOSITION OF STRONTIUM AND CALCIUM IN SNAIL SHELL

By PROF. G. M. ROSENTHAL, Jun.\*, DR. D. J. NELSON and DR. D. A. GARDINER

Radiation Ecology Section, Health Physics Division and Statistics Section, Mathematics Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee

THE chemical similarity between strontium and calcium has led to widespread use of <sup>87</sup>Sr-Ca ratios in interpreting the movement of <sup>87</sup>Sr in the environment and in metabolic processes<sup>1-3</sup>. While the ratios are useful in assessing the hazard to large sections of the population, they add little to our understanding of the fundamental relationship between strontium and calcium in organisms. Mollusc shell is considered to be a biogeochemical sink since incorporated materials are physiologically, as well as physically, isolated and unavailable for the animal's metabolism, which is not the case in the bone of rats or other mammals<sup>4</sup>. The amounts of newly deposited strontium and calcium in the shells of snails should therefore be related to the concentrations of these elements in experimental environments. The object of this research was to demonstrate precisely the relative effect of strontium and calcium concentrations in the environment on their uptake and incorporation into snail shell. This experiment with the freshwater snail, *Physa heterostropha* Say, differs significantly from other work on strontium and calcium uptake, in that the strontium and calcium concentrations of the experimental media were rigidly controlled by assay of the strontium and calcium content of all chemicals used. While there is a constant relationship between radioactivity and mass for a given radioisotope, a more useful comparison of the deposition of calcium and strontium may be obtained by using atom concentrations. In this experiment <sup>45</sup>Ca and <sup>87</sup>Sr were used as tracers and specific activities (radioactive atoms/total atoms of the same element) were used to determine deposition.

As the functional relationship between uptake of strontium and calcium in snail shell and the concentration

of these elements in the environment is unknown, one can do no better than to approximate it by a general form. One such form is a truncated Taylor series expansion:

$$Y = \beta_0 + \sum_{i=1}^n \beta_i X_i + \sum_{i,j=1}^n \beta_{ij} X_i X_j + \epsilon$$

in which  $Y$  is a response (either strontium uptake or calcium uptake),  $X_i$  and  $X_j$  are concentrations of strontium and calcium in the medium,  $\beta_0$ ,  $\beta_i$  and  $\beta_{ij}$  are unknown coefficients, and  $\epsilon$  is the deviation of the truncated Taylor series from the unknown functional form. From experimental evidence it is possible to estimate the unknown coefficients and to assess the significance of  $\epsilon$ . An efficient way to accomplish this is to perform an experiment based on an experimental design of the factorial type. The second order rotatable designs of Box and Hunter<sup>5</sup> are especially suited to this purpose.

If the scales of strontium concentration and calcium concentration in the medium are transformed to equal scales,  $U_1$  and  $U_2$ , a suitable design is obtained by selecting six combinations of  $U_1$  and  $U_2$  which are equally spaced on a circle in the  $U_1$ ,  $U_2$  plane together with that combination of  $U_1$  and  $U_2$  which is in the centre of the circle. If a number of snails are treated in each of the solution media corresponding to these points the several  $\beta$ 's of the Taylor series may be estimated and the significance of the  $\epsilon$  term assessed. In addition, the predicted response (that response calculated at a point in the  $X_1$ ,  $X_2$  plane using the estimates of the  $\beta$ 's) will have an uncertainty which is dependent only on the distance of the point from the centre of the design and not on its direction. Furthermore, this uncertainty will be relatively uniform throughout the experimental region if the centre point of the design is performed twice.

\* Present address: Biology Section, University of Chicago, Chicago, Illinois.

This seven-point design with the centre point duplicated was laid out in the  $U_1, U_2$  plane. Then, to achieve a random orientation, the design was rotated through a randomly determined angle ( $41^\circ$ ). The resulting co-ordinates were transformed back into units of strontium and calcium concentrations ( $X_1$  and  $X_2$ ) with the results as shown in the second and third columns of Table 1. These concentrations are essentially within the extreme range of strontium and calcium concentrations in natural waters.

Culture media were prepared from compounds of high purity, the strontium and calcium contaminants of which were accurately known. Reagent grade  $\text{CaCO}_3$  was further purified in the Analytical Chemistry Division of Oak Ridge National Laboratory and the compound used contained about  $1.8 \mu\text{g Sr/g CaCO}_3$ , the minimum level of detection. The basic medium was composed of  $0.5 \text{ g KNO}_3$ ,  $0.1 \text{ g NH}_4\text{H}_2\text{PO}_4$ ,  $0.25 \text{ g MgSO}_4$ ,  $0.1 \text{ g NaCl}$  and a trace of  $\text{FeCl}_3$  per litre. The solubility product constants were not exceeded for calcium or strontium salts in this medium. Calcium and strontium amendments in the form of chlorides were added to the basic medium according to the statistical design (Table 1). The pH of the media was adjusted to neutrality by the addition of small amounts of  $\text{NaOH}$ , and 200 ml. of solution were placed in 400-ml. 'Pyrex' beakers. Carrier-free  $^{88}\text{Sr}$  and  $^{45}\text{Ca}$  with negligible carrier ( $1.2 \times 10^{13}$  atoms/ml.) were added as tracers to all beakers in constant amounts.

Groups of ten snails, members of a graded series ranging in size from 9 mm to 13 mm long, were assigned randomly to each experimental concentration. The snails were maintained separately in beakers in a water bath at  $18^\circ\text{C}$ . Their food consisted of small amounts of the green, leafy portions of head lettuce. Minor amounts of calcium and strontium were included in the lettuce, which contained  $0.180$  and  $0.00062 \text{ mg/g}$ , respectively.

At the conclusion of the 21-day experimental period, snails were killed by freezing and the soft tissues were removed from the shell. Shells were then dried and weighed. Strontium-85 deposited in the shell was counted in a single-channel  $\gamma$ -scintillation spectrometer and  $^{45}\text{Ca}$ , as nitrate, in a  $\beta$ -liquid scintillation counter. Calcium-45 did not affect the  $^{88}\text{Sr}$  counting rate, but it was necessary to correct the  $^{45}\text{Ca}$  counts for a slight contribution from the  $^{88}\text{Sr}$  activity. Non-biological adsorption of both  $^{45}\text{Ca}$  and  $^{88}\text{Sr}$  was assessed by immersing fresh, 'Plasticine'-filled shells in the test solutions. However, adsorption of both elements was slight in comparison with biological deposition in the shells.

The average uptake of strontium and calcium in the snail shells is shown in the fourth and fifth columns of Table 1. The number of snails analysed at each experimental point is given in the last column. Losses occurred in the sample preparation, from mortality, and from snails crawling out of containers.

A rough idea of the variability in the data may be obtained by comparing the results of point 4 with those of point 8 which are the duplicated centre points. The standard deviations measured among snails treated alike are  $1.14 \times 10^{13}$  atoms/g for strontium and  $1.18 \times 10^{13}$  atoms/g for calcium with 39 degrees of freedom. However, the variability from one point of the design to another differed so much that the standard deviations at each point had to be considered.

The coefficients of the Taylor series were estimated by the method of least squares, weighting each observation by the reciprocal of the estimated variance at the point of observation.

Table 1

Experimental point	Design variables		Responses		No. snails
	Concentration in medium (atoms/ml.)		Uptake in shell (atoms/g)		
	Sr $\times 10^{13}$	Ca $\times 10^{13}$	Sr $\times 10^{13}$	Ca $\times 10^{13}$	
1	5.555	274.7	1.247	2.244	5
2	0.0111	162.5	0.00519	2.784	6
3	5.069	14.64	8.793	1.182	6
4	3.545	150.6	1.387	2.235	7
5	6.430	160.3	3.670	3.760	2
6	1.904	49.31	1.771	2.029	6
7	2.304	281.6	0.7676	3.145	8
8	3.545	150.6	1.326	2.011	7

Table 2. ANALYSES OF VARIANCE

Source of variation	Strontium		Calcium	
	D.F.	Mean square	D.F.	Mean square
Total	47		47	
Linear terms	3	105.89	3	73.04
Quadratic terms	3	13.20		
Residual	41	0.97	44	0.94

If the weights used were exact weights rather than estimated weights, probability tests would declare the residual mean squares non-significant and the other mean squares significant. Exact tests in the case of estimated weights are not known.

Table 3. REGRESSION COEFFICIENTS

Regression term	Sr uptake		Ca uptake	
	Coefficient $\times 10^{13}$	S.E. $\times 10^{13}$	Coefficient $\times 10^{13}$	S.E. $\times 10^{13}$
Intercept	96.78	63.2	19,800	4,970
Ca input	-2.12	0.50	54.14	15.94
Sr input	97.74	15.2	1,713	968
(Ca input) <sup>2</sup>	0.009	0.002		
(Sr input) <sup>2</sup>	11.88	3.37		
(Ca input) (Sr input)	-0.650	0.134		

For calcium uptake the data were adequately explained by the linear terms in the Taylor series. For strontium uptake, however, it was necessary to include all six terms of the truncated expansion. Reference to the analyses of variance in Table 2 will demonstrate the adequacy of the regression analysis on the two responses. The estimates of the coefficients in the regression equations are given in Table 3. For strontium these coefficients explain 90 per cent of the total variation and for calcium they explain 84 per cent.

The deposition of calcium and strontium by snails is illustrated graphically in Figs. 1 and 2, respectively. These are response surfaces calculated from a least squares fit of the data. Calcium uptake is represented best by a plane surface which is expressed mathematically as follows:

$\text{Ca uptake} = 19,800 + 54.14 \text{ Ca input} - 1,713 \text{ Sr input}$   
with uptake in atoms  $\times 10^{13}/\text{g shell}/21 \text{ days}$  and input in atoms  $\times 10^{13}/\text{ml}$ .

Fig. 1. Calcium deposition in snail shell as a function of environmental Ca and Sr concentrations ( $30.1 \times 10^{13}$  atoms Ca/ml. = 20 p.p.m. Ca;  $0.686 \times 10^{13}$  atoms Sr/ml. = 1 p.p.m. Sr).

Fig. 2. Strontium deposition in snail shell as a function of environmental Ca and Sr concentrations ( $30.1 \times 10^{18}$  atoms Ca/ml. = 20 p.p.m. Ca,  $0.685 \times 10^{18}$  atoms Sr/ml. = 1 p.p.m. Sr)

Calcium carbonate is the basic structural component of mollusc shells, and a slight increase in growth is indicated by an increasing uptake of calcium with increasing calcium concentrations. However, growth differences in the seven experimental environments, as measured by calcium deposition, were only 0.17 times as much as the differences in the environmental calcium concentrations. While growth increased directly with the calcium concentration, the increases were relatively small when compared with the differences in environmental calcium concentrations.

The uptake of calcium is conservative when compared with that of strontium, which is best represented by a quadratic expression:

$$\text{Sr}_{\text{uptake}} = 98.78 - 2.12 \text{Ca}_{\text{input}} + 97.74 \text{Sr}_{\text{input}} + 0.009 (\text{Ca}_{\text{input}})^2 + 11.88 (\text{Sr}_{\text{input}})^2 - 0.695 (\text{Ca}_{\text{input}}) (\text{Sr}_{\text{input}})$$

with uptake in atoms  $\times 10^{16}$ /g shell/21 days and input in atoms  $\times 10^{18}$ /ml.

The range of strontium deposition in the snail shells was 2.9 times the range of environmental concentrations.

The surfaces depicting the deposition of calcium and strontium in Figs. 1 and 2 are based on least squares fits to the data in Table 1. Inspection of the data and Fig. 1 and Fig. 2 viewed grossly as plane surfaces indicates that deposition of both calcium and strontium in the shell of *P. heterostrophia* depends primarily on the respective concentrations of these elements in the immediate environment. Failure of the planes to intersect the zero axis is a geometric artefact arising from the extrapolation of the equations to zero; obviously there can be no incorporation of calcium or strontium when none is present. A slight negative interaction, that is, of environmental strontium on calcium deposition, and vice versa, is also evident from the skewed appearance of the incorporation planes. Biologically this interaction is probably best explained in the conventional terms of competition for incorporation sites.

The dotted line in Fig. 2 represents the minimum strontium deposition for the various combinations of strontium and calcium in the environmental media. To the right of the dotted line there is essentially a linear increase in strontium uptake with increasing environmental strontium concentrations. At lower calcium concentra-

tions (in this portion of the surface) there is a relatively greater uptake of strontium. This suggests a simple substitution of strontium uptake for that of calcium by snail shell when environmental calcium is deficient; it is in accord with the observations and conclusions of Odum<sup>8</sup> and Likens *et al.*<sup>9</sup> regarding strontium uptake by snails under conditions of high environmental strontium-calcium ratios (at low calcium concentrations). At all points to the right of the dotted line strontium uptake increases with increasing environmental strontium concentrations and decreases with increasing environmental calcium concentrations. To the left of the dotted line the opposite behaviour is noted, that is, increased environmental strontium depresses strontium uptake and increased environmental calcium enhances strontium uptake.

This phenomenon, the reversal of the relation of strontium deposition rate to strontium and calcium concentrations, is unexpected. Two possible explanations may be offered: (1) it is brought about by different reactions, purely chemical in nature, based largely on concentration differences; and (2) it is primarily biological and probably associated with a threshold or compensatory effect. There is no evidence, either specific or general, for accepting the first explanation. The effect would seem to be related to some physiological property of the mantle cells, possibly to membrane phenomena or secretory activity, and warrants further investigation.

Because of the interacting effects of different environmental strontium and calcium concentrations on strontium and calcium uptake, the presence of adventitious strontium in calcium compounds is an important factor in interpreting strontium uptake data. Recent analyses<sup>10</sup> of various reagent grade compounds show adventitious strontium ranges from 140 to 1,615  $\mu\text{g}$  strontium/g calcium. Hence, in a  $^{87}\text{Sr}$  uptake experiment in which the basic calcium content is changed by calcium amendments, there is also a proportionate change in the strontium concentration, thereby confounding the results by the unsuspected alteration of both important variables. Hegsted and Breenahan<sup>11</sup> noted the adventitious strontium in rat food, and observed that small additions of stable strontium to the diet enhanced the deposition of either  $^{45}\text{Ca}$  or  $^{87}\text{Sr}$ . Only with larger additions of stable strontium to the diet was a diluent effect of strontium noted.

Stable strontium added to the soil resulted in a similar effect on the uptake of  $^{87}\text{Sr}$  by ladino clover<sup>12</sup>. That the diluent effect of small amendments of stable Sr is generally ineffective was noted by Thompson<sup>13</sup>. The obvious correlative is that many organisms simply increase the total amount of strontium in their bodies when the environmental concentration is increased. In other words, the biological systems are not saturated with respect to strontium and only when the system becomes saturated does isotopic dilution become effective.

Much research on  $^{87}\text{Sr}$  and calcium in the environment has had an ultimate objective of obtaining information that would permit accurate prediction of  $^{87}\text{Sr}$  uptake by man or other organisms<sup>14,15</sup>. Ratios involving  $^{87}\text{Sr}$  and calcium<sup>1,9</sup> have been used frequently as a predictive tool. Since there is a large volume of information on the distribution of calcium in Nature, these ratios have the obvious feature of utilizing existing information along with new data on  $^{87}\text{Sr}$ . Because of the variability of these ratios, their limitations for prediction have been recognized<sup>16,17</sup>. A portion of the variability in  $^{87}\text{Sr}$  uptake by plants has been associated with the availability of calcium in soil<sup>18</sup>. An investigation of strontium and calcium uptake by algae<sup>19</sup>, under conditions similar to those of this experiment with snails, showed that uptake of either strontium or calcium was dependent primarily on the concentrations of the respective elements in solution. With either the algae, which have a rapid metabolic turnover of strontium, or the snail shell, which is a biogeochemical sink, it is clear that strontium uptake

is more closely associated with environmental strontium concentrations than with calcium concentrations. The results of these experiments show the advisability of considering stable strontium concentrations in an interpretation of the behaviour of  $^{87}\text{Sr}$  in biological systems.

## GEOCHRONOLOGY OF THE LEWISIAN BASEMENT NEAR LOCHINVER, SUTHERLAND

By DR. C. R. EVANS\*

Geological Age and Isotope Research Group, Department of Geology, University of Oxford

THIS article is a summary of part of a detailed investigation of the petrology, structural geology and isotopic geology of a small but complex area of Lewisian gneiss near Lochinver on the north-west coast of Scotland. The first systematic study of the Lewisian resulted in the comprehensive 1907 memoir by Peach *et al.*<sup>1</sup>, who identified three pre-Torridonian events, that is: (1) the formation of the fundamental pyroxene-bearing complex; (2) intrusion of north-west trending basic and ultrabasic dykes; (3) deformation and metamorphism of the dykes.

This chronological division of the Lewisian was enlarged on by Sutton and Watson<sup>2</sup>, who called the predyke (granulite facies) metamorphism 'Scourian' and the post-dyke (amphibolite facies) metamorphism 'Laxfordian'. The conclusions of these earlier workers have since been confirmed by the isotopic dating of Giletti *et al.*<sup>3</sup>, who concluded that the Scourian is older than 2,460 m.y. and that the Laxfordian is about 1,600 m.y. old. More recently, Evans and Tarney<sup>4</sup> have shown that the dykes were intruded between 2,200 and 1,900 m.y. ago.

**Isotopic results from Lochinver.** The strontium composition of whole-rock samples from each metamorphic facies in the Lochinver district is presented in Table 1. The extremely low rubidium content makes it impossible to determine the primary age of these rocks, but it does allow us to estimate the initial composition of the strontium. Since the present complex has a strontium isotopic composition comparable with the mantle<sup>5</sup>, it is unlikely that these rocks contained normal crustal abundances of rubidium for any great length of time, if ever. A normal crustal Rb/Sr ratio of 0.25 would result in a detectable increase in the  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio in about 300 m.y. Similarly, if the acid gneiss represents pre-Scourian granite from which the potassium and rubidium have been removed by metasomatism, the time-interval between their original differentiation and later remobilization could not have been more than about 100 m.y. The pre-Scourian complex may thus represent either a basal layer in the Earth's crust which was depleted in volatile elements by a continuation of the same process by which it differentiated from the mantle, or it may have been a normal crustal series of rocks which lost its volatile elements during a profound metamorphism shortly after its original differentiation.

The existence of very old basement rocks with a strontium isotopic composition comparable with the present-

day mantle suggests that considerable caution must be used in applying Hurley's<sup>6</sup> strontium-87 model of continent formation. The addition of rubidium to such material during a subsequent metamorphic episode would produce a result isotopically indistinguishable from new crustal material derived from the mantle. Precisely such a metasomatic origin has been postulated<sup>7</sup> for the alkali-rich northern part of the Lewisian. If rocks of similar isotopic composition and Rb/Sr ratio to those of the Lochinver district composed a significant part of the early sialic crust, the proposed model dates the addition of rubidium to this material rather than the addition of large quantities of new sial to the continents.

**The Scourian episode.** Scourian granulite facies metamorphism produced a series of hypersthene-bearing rocks exposed to the south of Lochinver<sup>8</sup>. Potassium-argon dating of basic and ultrabasic granulite facies materials (Table 2, A) indicates a minimum age of at least 2,600 m.y. for this event. In interpreting the apparent ages obtained on different materials from these rocks, it must be remembered that they were formed under great pressure, and have been reheated to some extent by subsequent thermal events which caused complete amphibolization only a few kilometres away. Thus, some extremely retentive materials may contain excess or inherited argon<sup>9-12</sup>, while the least retentive minerals have probably lost argon.

Biotite and brown hornblende (samples 290 and 547) appear to be the least retentive minerals of the granulite facies suite. It is well established that biotite loses argon readily on reheating. Since ex-solution of dusty, opaque ore from brown hornblende is one of the first indications of retrograde amphibolization in this area, it is not surprising that it also has a poor retentivity. On the other hand, the pale green hornblende from ultrabasic rocks (494 and 610) appears to be an excellent mineral for potassium-argon dating. The two samples have potassium contents differing by a factor of two, yet give the same age to within 1 per cent, indicating little or no inherited argon. The apparent age of 2,620-2,630 m.y. obtained on these hornblendes is some 4 per cent greater than the oldest age obtained on biotite in this investigation.

Plagioclase and hypersthene each yield apparent ages of 2,860 m.y., but it is not known whether this represents the true age of their formation and cooling, or a spuriously high age due to excess argon. Augite from a biotite-augite pod (sample 546) clearly contains a great deal of excess argon, giving an apparent age of about 5,200 m.y.,

\* Present address: Imperial Oil Enterprises, Ltd., 500 Sixth Avenue, South West, Calgary, Alberta, Canada.

as compared with 2,520 m.y. for the biotite. The calculated whole-rock age of this sample is  $2,600 \pm 60$  m.y., suggesting that much of the excess argon in the augite may have been derived from the biotite.

From the results obtained on the most retentive hornblende and biotite samples, it is concluded that Scourian, granulite facies metamorphism occurred at least 2,600 m.y. ago, and that it may be of considerably greater age.

**Intrusion of pegmatites.** The Scourian gneiss is intruded by alkali-rich pegmatites, which occur as dyke-like bodies. The pegmatite dykes south of Lochinver have been dated by Rb-Sr at  $2,250 \pm 50$  m.y. (ref. 7) and will be discussed in detail in a later communication. They appear to belong to the same generation of pegmatites that were dated by Giletti *et al.*<sup>8</sup>

**The Inverian episode.** Following the intrusion of pegmatites and prior to the intrusion of the north-west trending basic dykes, parts of the Lochinver district together with large portions of the central block of Lewisian gneiss underwent almandine amphibolite facies

metamorphism and structural deformation under a north-east-south-west principal stress. The name 'Inverian' is proposed for this previously unrecognized event, and the type area is specified as the lower three kilometres of the River Inver<sup>9</sup>.

Potassium-argon determinations on hornblende and biotite from amphibolite facies gneiss range from 2,100 m.y. to 1,560 m.y. (Table 2, B). Both hornblende and biotite from this suite are thoroughly recrystallized and readily distinguished petrographically from their counterparts in the pre-existing granulite facies suite. Since it is unlikely that any of the measured argon was generated prior to amphibolization, the 2,100 m.y. age obtained from the most retentive hornblende is taken as the best estimate of the minimum Inverian age.

The large spread in apparent ages of amphibolite facies materials is thought to reflect varying degrees of argon retentivity during the 1,580 m.y. Laxfordian reheating (see following). In this respect it should be noted that hornblende again appears to be more retentive than biotite.

\* Analysed by emission spectrograph.  $\lambda = 1.47 \times 10^{-11}$  yr<sup>-1</sup>.

The possibility of excess argon in the hornblende samples is once more discounted due to the lack of any relationship between potassium content and apparent age. While the leakage of argon during the reheating of these older amphibolites casts some doubt on the proximity of the 2,100 m.y. minimum age to the actual event, this same phenomenon makes it possible to estimate a maximum age of 2,350 m.y. for the Inverian from its effect on the least retentive minerals in the neighbouring Scourian gneiss.

The rubidium-strontium age of the pre-Inverian pegmatites (2,250 m.y.) improves this inferred maximum by about 4 per cent. The minimum potassium-argon limit was improved by a similar amount by a rubidium-strontium age of 2,190 m.y. obtained on a relatively fresh picrite dyke which cuts across folded and amphibolized Inverian gneiss<sup>4</sup>.

**The Laxfordian episode.** While the central belt of Lewisian gneiss escaped the major metasomatic effect recorded in the Laxford area, Laxfordian deformation is clearly recorded in the post-Inverian dykes near Lochinver, where it takes the form of brittle shears accompanied by epidote amphibolite facies metamorphism.

This event was extensively dated as 1,500–1,600 m.y. in its type area by Giletti *et al.*<sup>3</sup>. Potassium-argon results on materials taken from amphibolized dykes and shears in the Lochinver area (Table 2, C) are in general agreement, with an average of 1,580 m.y. However, the rubidium-strontium results on metamorphic biotites (Table 3) are distinctly lower, indicating an age of about 1,420 m.y. Although little is known about the nature of this later event, it appears to have affected the rubidium-strontium age of Scourian biotite as well, causing extreme discordance between the potassium-argon age of 2,520 m.y. for sample 546 and the rubidium-strontium age of 1,400 m.y. for the same sample. Giletti *et al.*<sup>3</sup> attribute the spread in their Laxfordian ages to mild reconstitution later than 1,160 m.y., but Evans and Park point out that a spread in 'Laxfordian' ages might well be expected in view of the multiphase nature of this event in the Gairloch district to the south.

Analytical methods are those described by Evans and Tarney<sup>4</sup>.

**Conclusions.** (1) The pre-Scourian complex was derived from a source region with a strontium 87/86 ratio lower than most basic igneous rocks. If this complex ever contained normal crustal abundances of rubidium, it was removed within a short time after original differentiation from the mantle.

(2) Scourian granulite facies metamorphism occurred at least 2,600 m.y. ago.

(3) Potassic pegmatites were intruded about 2,250 m.y. ago.

(4) Inverian amphibolite facies metamorphism occurred about 2,200 m.y. ago.

(5) A period of dyke intrusion began immediately following Inverian metamorphism, and may have continued for as long as 300 m.y., during which time the country rock became progressively cooler.

(6) Parts of the area were affected by Laxfordian reheating about 1,580 m.y. ago.

(7) An event of unknown character appears to have purged the radiogenic strontium from metamorphic biotites about 1,400 m.y. ago.

## FAR INFRA-RED FARADAY ROTATION IN A PLASMA

By A. N. DELLIS, W. H. F. EARL, A. MALEIN and S. WARD

U.K. Atomic Energy Authority, Culham Laboratory, Abingdon, Berkshire

**F**ARADAY rotation in a laboratory plasma has been previously observed both in the optical region<sup>1</sup> and at an infra-red wave-length of  $3.39\mu$  (ref. 2). Rotations of several degrees per kilogauss are reported here, observed using a pulsed water-vapour laser as a source. This laser, developed at Services Electronics Research Laboratory, Baldock, by Large and Hill<sup>3</sup>, gives monochromatic  $27.9\mu$  wave-length pulses of about 1  $\mu$ sec duration and 10-W peak power. The design is based on the observations of laser action in water-vapour by Crooker *et al.*<sup>4</sup>.

The Faraday rotation in radians, for propagation through a plasma of electron density  $n$  cm<sup>-3</sup> in a direction parallel to a constant superimposed magnetic field  $B$  gauss, is given by:

$$\psi = 2.63 \times 10^{-17} n B l \lambda^2 \quad (1)$$

where  $l$  is the path-length in the plasma and  $\lambda$  is the free-space wave-length of the radiation, both in cm. In the experiments described here,  $B$  and  $l$  are known and  $n$  is deduced from the measured value of  $\psi$ . Since  $\psi$  is

Fig. 1

proportional to  $\lambda^2$ , the rotation is 68 times that which would occur for  $\lambda = 3.39\mu$  and 1,950 times that for  $\lambda = 6328 \text{ \AA}$ , the wave-lengths at which rotation has been previously observed.

Fig. 1 shows the arrangement of the apparatus. The plasma, length  $l = 200 \text{ cm}$  between the end electrodes, has already been described in connexion with experiments on hydromagnetic wave propagation<sup>5</sup>. The uniform axial magnetic field of up to 6 kG varies negligibly during the 1-μsec laser pulse. Polyethylene vacuum windows were used at each end of the plasma column, their transmission loss being small at 27.9μ wave-length. The input polarizer, P1, consists of 10 sheets of 37μ thickness and 10 sheets of 52μ thickness polyethylene sheet, inclined at the Brewster angle (55°) to the incident laser radiation. Such polarizers were described by Mitsuishi *et al.*<sup>6</sup>. P1 can be rotated about an axis lying along the propagation direction, the angular setting  $\theta$  being registered on a scale. Tests with two identical polarizers showed the intensity of transmitted power in the crossed position to be 1.8 per cent of that in the aligned position.

The polarization analyser is P2 which consists of two vertical plates of high resistivity silicon, each of thickness

this value  $\theta_0$  is about 45° to the vertical. If  $\theta = \theta_0 + \phi$ , then:

$$V_i/V_r = \cot^2 \theta_0 \tan^2 (\theta_0 + \phi) \approx \tan^2 (45^\circ + \phi) \quad (2)$$

if  $\theta_0$  is near 45°, a relation which was verified experimentally over a 180° range of  $\phi$ . With a plasma present, P1 is rotated so as to keep  $V_i$  and  $V_r$  equal. The polarization of the radiation leaving the plasma is therefore still as before, the rotation of P1 giving the magnitude and sense of the Faraday rotation directly. For a ratio  $V_i/V_r$  not exactly equal to unity the small correction to give  $\theta_0$  is calculated from (2).

Oscillograms of  $V_i$  and  $V_r$ , with no plasma present, are shown in Fig. 2 ( $V_i$  is the upper trace in all the oscillograms). The three shots shown were taken with  $\theta = 47.5^\circ$  and the values of  $\theta_0$  are calculated as 46.5°, 48° and 48.5° for Figs. 2a, b and c, respectively. The initial small spike on these oscillograms is due to electrical interference, picked up from the laser power supply. With an argon plasma, initial gas pressure 37 mtorr, having an axial field of 4.6 kG, it was necessary to reset P1 to  $\theta \approx 33^\circ$  to restore equality of  $V_i$  and  $V_r$ . Fig. 3

Fig. 2. Signals from the infra-red detectors at 2 μsec/cm sweep speed.  $V_i$  (upper traces) and  $V_r$  (lower traces) for  $\theta = 47.5^\circ$  with no plasma present

Fig. 3. Signals from the infra-red detectors at 2  $\mu\text{sec}/\text{cm}$  sweep speed.  $V_t$  (upper traces) and  $V_r$  (lower traces) for  $\theta$ ,  $30^\circ$  with an argon plasma.

Fig. 4. Measured values of  $\theta$ , on successive shots.

shows three typical oscillograms, taken with this argon plasma, for  $P_1$  set at  $\theta = 30^\circ$ . The values of  $\theta$ , the angle to which  $P_1$  should have been set to make  $V_t = V_r$ , according to expression (2), are  $34^\circ$ ,  $30^\circ$  and  $35.5^\circ$ , respectively, for Figs. 3a, b and c. The time was 500  $\mu\text{sec}$  after the start of the current pulse.

Series of shots with plasma present were interposed between series with no plasma, and the resulting values of  $\theta$ , deduced as already described, are plotted against shot number in Fig. 4. Two definite values of  $\theta$ , should result for these two conditions, their difference being the magnitude of the Faraday rotation,  $\psi$ . In fact, a spread of values was observed, though with well-defined mean values, drawn as solid lines in Fig. 4. The standard deviation is about  $2^\circ$  so that  $\psi$  is taken as  $15^\circ \pm 3^\circ$ . Substituting the previously known values  $l = 200$  cm and  $B = 4.6 \pm 0.1$  kG in expression (1) yields:

$$n = (1.4 \pm 0.3) \times 10^{18} \text{ cm}^{-3}$$

The large spread observed in the values of  $\theta$ , is unsatisfactory, being much greater than the fundamental limit set by detector noise. The spread is thought to be due to the effects of fluctuations in polarization and mode pattern of the laser from shot to shot combined with cross-polarization leakage in  $P_1$  and non-identical optics in the two detector channels.

There is no measurable Faraday rotation, due to the vacuum windows, with a pulsed magnetic field of 6 kG but no plasma.

Using a helium-neon CW gas-laser to measure  $n$  interferometrically, by the method originally described by

Ashby and Jephcott<sup>7</sup>, though detecting the  $3.39\mu$  wavelength directly, a value:

$$n = (1.33 \pm 0.08) \times 10^{18} \text{ cm}^{-3}$$

was obtained for the same argon plasma. A time-resolved interferogram is shown in Fig. 5, the time at which the Faraday rotation was measured being indicated as  $t_F$ . The upper trace is a plot of the plasma gas current, the peak value being 20 kA. Fringes occurring at late times are not shown in this figure.

Faraday rotation was also measured in a hydrogen plasma in the same tube, the initial gas pressure being 50 mtorr. Magnetic field values 3.0, 4.0 and 6.0 kG, all  $\pm 0.1$  kG, were used. The results, taken at a time 100  $\mu\text{sec}$  after peak current (40 kA), are given in Table 1.

Table 1

$B$ (kG)	$\psi$ (degrees)	$n$ , $\text{cm}^{-3}$ calculated
3.0	$33 \pm 7$	$(4.7 \pm 1.0) \times 10^{18}$
4.0	$45 \pm 7$	$(4.7 \pm 0.8) \times 10^{18}$
6.0	$60 \pm 10$	$(4.3 \pm 0.6) \times 10^{18}$

A  $3.39\mu$  wave-length interferometer measurement was carried out for the condition with 6.0 kG and gave:

$$n = (4.3 \pm 0.2) \times 10^{18} \text{ cm}^{-3}$$

Faraday rotation at  $\lambda = 27.9\mu$  in a plasma has thus been clearly demonstrated. In the experiment described here, where the magnetic field strength was already known, it has resulted in electron density measurements in agreement with those derived from an interferometer

Fig. 5. Interferogram in the argon plasma at  $\lambda = 3.39 \mu$  (lower trace). The upper trace shows the gas current pulse. Sweep speed is 100  $\mu\text{sec}/\text{cm}$ .

working at  $\lambda = 3.39\mu$ . While the accuracy achieved was poorer than that of the latter method, considerable refinement of the accuracy should be possible. Moreover, the difficulties which arise in the interferometric method from the need to follow increases and decreases of density to a point where the density is known do not occur, and a spot density measurement can be made in a fraction of a microsecond without reference to the previous or subsequent behaviour of the plasma.

In the general case, however, when the magnetic fields are not known, the two methods are complementary; the Faraday rotation gives information on the magnetic field while the interferometer does not. Since the effect on an infra-red beam of transverse components of the magnetic field is normally negligible compared with that of very much smaller longitudinal components, the

Faraday rotation along a path-length  $l$  measures  $\int nB \cdot ds$

while the phase shift measured interferometrically is proportional to  $\int_0^l n \cdot ds$ .

We thank Dr. R. J. Bickerton for his advice, and Mr. B. Parham for help with the measurements. The experiments were made possible by the generous loan of the laser from Services Electronics Research Laboratory, Baldock, and by the supply of infra-red detectors from the Radar Research Establishment, Malvern.

## EVIDENCE FOR AN UNUSUAL SOURCE OF HIGH RADIO BRIGHTNESS TEMPERATURE IN THE CRAB NEBULA

By D. A. HEWISH and S. E. OKOYE

Mullard Radio Astronomy Observatory, Cavendish Laboratory, University of Cambridge

RECENT observations using both the lunar occultation technique<sup>1</sup> and an interferometer of high resolution<sup>2</sup> have disclosed the presence of a component of small angular diameter in the Crab Nebula which becomes pronounced at low frequencies. The radio spectrum of this component has a steep gradient of  $-1.2$  and accounts for about 20 per cent of the total emission from the nebula at a frequency of 38 Mc/s. Further observations of the nebula, carried out in connexion with an International Quiet Sun Year programme during 1963-1964, have yielded the additional evidence that this component exhibits remarkable fluctuations of intensity which cannot be ascribed to ionospheric scintillation since other sources do not show similar effects. The occurrence of the fluctuations exhibits a pronounced annual variation which can be readily explained if the phenomenon is due to interplanetary scintillation.

Interplanetary scintillation, arising from the passage of radiation through irregularities of electron density in the interplanetary medium, is a diffraction effect which is confined to radio sources of exceedingly small angular diameter. Already it has been used to place upper limits on the angular dimensions of 'quasi-stellar' sources<sup>3</sup>, and the present observations may only be accounted for if the small component of the Crab Nebula has an angular diameter  $\sim 0''.1$ . This result raises interesting questions concerning the physical nature of the source since it implies an exceptionally high brightness temperature which cannot be accounted for by synchrotron emission.

The observations at 38 Mc/s were carried out with an interferometer comprising two corner-reflectors of length 800 ft. and 3,000 ft. on an east-west baseline of 10 km. At this separation the Crab Nebula is largely resolved and the response is entirely due to the component of small angular diameter. Some additional observations were made with an interferometer of low angular resolution consisting of two halves of the 3,000 ft. corner-reflector; in this case only 20 per cent of the response is due to the small-diameter component and the fluctuations were not as prominent on the records. For both systems similar phase-switching receivers were used with a time constant of 2 sec. Typical recordings of the fluctuation phenomenon are shown in Fig. 1a and c. It is seen that the Crab Nebula exhibits pronounced variations of apparent intensity while 3C123, which is separated in declination

by only  $7.5^\circ$  and transits roughly 1 h earlier, yields a smooth fringe pattern. Similar records are obtained on most occasions.

The fluctuations exhibit considerable day-to-day variations, but observations over a period of 12 months

Fig. 1. a and c, Typical recordings of intensity fluctuations of the Crab Nebula; b, a record showing the marked decrease of fluctuation when the Crab Nebula was near the Sun. Time scale in minutes

Fig. 2. Weekly means of the average intensity fluctuation (per cent) indicating a systematic annual variation

have disclosed a systematic annual variation. Weekly means of the average deviation of apparent intensity, expressed as a percentage of the mean intensity, are shown in Fig. 2. It is seen that the fluctuations are most pronounced in April and August, falling to lower values during October–February and vanishing almost completely over a period centred on mid-June. During the winter months, when the source is in transit during the night, ordinary ionospheric scintillation is of frequent occurrence, thus rendering the observations uncertain. On several occasions, however, free of ionospheric scintillation, recordings showing the absence of fluctuations were obtained.

The time-scale of the fluctuations is not easy to ascertain owing to the short interferometric fringe-period of 12 sec. Frequently successive positive and negative fringe maxima show unrelated fluctuations so that the time-scale must be of the order of a few seconds. Variations at an appreciably faster rate would have been smoothed by the 2-sec time constant.

An attempt to detect angular deviations associated with the intensity fluctuations was carried out during April when the fluctuations were most pronounced. An analysis of the time intervals between successive fringes indicated no significant fringe displacements, from which it was deduced that the direction of arrival of the radiation was unperturbed within  $\pm 25''$ . On the supposition that the fluctuations are due to random diffraction by phase-changing irregularities, considerably larger angular deviations would be expected unless the scale of the diffraction pattern was appreciably larger than the baseline of the interferometer. It may thus be deduced that the scale of the diffraction pattern is greater than 10 km. Independent evidence for a scale exceeding 10 km also comes from the high degree of correlation which is noticed for large fluctuation maxima observed simultaneously on the interferometers of high- and low-angular resolution.

In seeking an explanation of the fluctuations it is apparent that intrinsic variations of the source itself cannot reasonably account for the annual variation and for the fast fluctuation rate. Ionospheric scintillation can be excluded for several reasons; the fluctuations are most pronounced at times well removed from the usual nocturnal scintillation maximum and they are not observed on other radio sources. Again, large intensity variations in the diffraction pattern of phase-changing irregularities can only occur beyond a critical distance of the order  $L/4\phi$  where  $L$  is the scale of the irregularities and  $\phi$  the typical angular deviation<sup>1</sup>. Putting  $L \geq 10$  km, the minimum possible value, and  $\phi \leq 25''$ , we deduce that the irregularities must be situated at a distance of at least  $2 \cdot 10^4$  km, which places them far beyond the ionosphere.

The only satisfactory explanation which can be suggested is that the fluctuations are caused by interplanetary scintillation as has been observed for quasi-stellar radio sources<sup>2</sup>. The notable disappearance of scintillation during June, when the Crab Nebula passed within a small angular distance of the Sun, is then explained as a blurring

of the diffraction pattern due to the finite diameter of the radio source. This effect has already been predicted and suggested as a technique for angular diameter measurement<sup>3</sup>; it has also been observed<sup>4</sup> at 178 Mc/s on the source 3C2. It is important to note that the disappearance of the fluctuations is an effect which may be examined independently from the decrease of fringe amplitude which is observed when the source reaches a smaller angular distance from the sun, and which has been used previously to examine the outer corona<sup>5</sup>. Both phenomena are, indeed, manifestations of the same diffracting irregularities, but scintillation only occurs for a source having a sufficiently small angular diameter.

It is known, both from previous measurements<sup>6</sup> and from the decrease of fringe amplitude observed in 1964, that the angular scattering imposed by the interplanetary medium has a magnitude of about  $0.25''$  at a distance of 0.5 A.U. for a frequency of 38 Mc/s. Assuming a gaussian angular spectrum  $\exp(-\phi^2/\phi_0^2)$  it follows<sup>7</sup> that the autocorrelation function of the diffraction pattern in a plane perpendicular to the line of sight is given by  $\rho(\xi) = \exp[-(\pi^2 \xi^2 \phi_0^2/\lambda^2)]$  where  $\lambda$  is the wave-length. It may be shown<sup>8</sup> that the degree of scintillation is then reduced by one half when  $\lambda/\pi\phi_0\theta_0 H \sim 1$ , where  $\theta_0$  is the diameter (to  $1/e$ ) of a circularly symmetrical gaussian source and  $H$  is the distance of the diffracting irregularities from the plane of the observation. Putting  $\phi_0 \sim 0.25''$  and  $H = 0.8$  A.U., corresponding to the observations of mid-May when the scintillation was considerably reduced, we derive  $\theta_0 \div 0.1''$  for the angular diameter of the radio source in the Crab Nebula.

The physical size of a source subtending a diameter of  $0.1''$  at the distance of the Crab Nebula is approximately  $10^{-3}$  parsec and the brightness temperature required to account for the observed radio flux is then about  $10^{14}$  °K. Optical continuum radiation from the central portions of the nebula can be explained<sup>9</sup> as synchrotron radiation produced by relativistic electrons having energies up to  $10^{13}$  eV. Energies  $> 10^{13}$  eV are needed to account for the high radio brightness temperature in terms of synchrotron emission, but the magnetic field then has to be  $< 10^{-8}$  oersteds which is much smaller than the suggested value of  $10^{-4}$  oersteds. Brightness temperatures of the same order are, however, observed during intense radio outbursts associated with solar flares. It has already been noted that a continuous injection of energetic electrons is needed to account for the optical radiation, and the possibility has been suggested that these electrons are derived from an active remnant of the original supernova explosion<sup>10</sup>. In this case the remnant might be expected to show continuous flare-type phenomena on a sufficiently grand scale to account for the radio emission. Alternatively, there may be some connexion between the radio emission and the light-ripples which have been observed near the centre of the nebula.

It is clear that further measurements, particularly at longer wave-lengths, are needed to establish the spectrum of the source with greater accuracy. It might also be interesting to seek for secular variations of the radio emission since it would be surprising if such a physically small source radiated steadily for long periods. An examination of previous recordings of the Crab Nebula made during an investigation of coronal scattering in April 1962 has revealed similar fluctuations of intensity, so the source appears to have shown little change during at least two years.

## ASTROPHYSICS

### Observations of the Sun in the Extreme Ultra-violet made from a Stabilized Skylark Rocket

THE successful launching of the first two stabilized *Skylark* rockets from Woomera, South Australia, in August and December 1964 was recently reported together with the results obtained by experiments prepared at Culham Laboratory<sup>1</sup>. These flights demonstrated accurate solar pointing and obtained photographic records of the extreme ultra-violet spectrum of the Sun and the distribution of extreme ultra-violet radiation from the solar disk. The third stabilized *Skylark* rocket was launched on April 9, 1965, at 0100 U.T. and carried two Culham experiments. These were particularly successful, giving new data on the chromospheric and coronal ultra-violet spectrum and new extreme ultra-violet spectroheliograms at shorter wave-lengths. This communication presents the latest results.

*New ultra-violet spectra of the solar chromosphere and corona.* The instrumentation prepared for the recent flight included a normal incidence grating spectrograph with a servo-controlled alignment system similar to that used on the first two payloads. An electromagnetic actuator developed by Sperry Gyroscope Co., Ltd., Bracknell, was used to control the mirror alignment and the spectrograph was set to cover the wave-length range 950–2950 Å. The alignment system stabilized an image of the Sun so that the spectrograph slit was set 10 sec of arc outside of the solar limb in order to view the chromospheric and coronal layers separately from the bright solar disk. The rocket attitude control unit and the optical alignment system both operated correctly and the solar image was stabilized at the spectrograph slit with an accuracy (root mean square) of  $\pm 2$  sec of arc. This coronagraphic type of experiment based on the accurate control of the image position enabled the spectrograph to record new emission lines originating in the chromosphere and corona at wave-lengths where the solar spectrum is normally dominated by emission from the photosphere.

Fig. 1 shows a part of the spectrum recorded during an exposure for 95 sec at a mean altitude of 150 km. The

2795 Mg II — 2803 Mg II

Fig. 2. Chromospheric emission of MgII doublet (*Skylark* SL 303, April 9, 1965)

central strip of the spectrum is produced by that region of the chromosphere and corona which was imaged on the centre of the slit, although there is some increase in the length of the spectral lines caused by astigmatism in the spectrograph. The spectrum recorded along the outer borders of the film results from photospheric radiation which is scattered from the primary concave mirror and enters the full length of the spectrograph slit. It therefore represents the spectrum of the total Sun and can be compared at any wave-length with the central strip of spectrum which represents the chromospheric and coronal emission. This is illustrated in Fig. 2, which shows a detail of the spectrum at 2800 Å. The resonance doublet ( $3s^1S - 3p^1P$ ) of MgII is seen in the photospheric spectrum as two strong absorption lines with faint emission cores, but the central limb spectrum shows the two emission lines as the dominant features. Many emission lines are recorded in the central spectrum which do not appear in the outer borders and have not previously been observed in the solar spectrum. A pure continuous spectrum is also observed for the first time in this region.

A preliminary analysis of the new spectra shows many features of interest. The strong line at 1908.6 Å is identified as the  $2s^1S_0 - 2p^1P_1$  intercombination line

Fig. 1. Solar limb spectrum 1800–2300 Å (*Skylark* SL 303, April 9, 1965)

of CLII which will determine the  $2p\ ^3P_1$  term-level. The similar transition in SiIII produces the adjacent strong line at 1892 Å. Many strong emission lines between 2000 Å and 2400 Å cannot be identified with certainty and probably include forbidden transitions in highly ionized atoms related to the visible emission line spectrum of the corona. A complete analysis of the new solar spectra is now in progress and will be published in due course.

**Monochromatic extreme ultra-violet solar photography.** Photographs of the Sun in soft X-rays have been previously obtained using pinhole cameras carried in stabilized rockets<sup>1-3</sup>. The wave-length response of this type of camera is determined by the transmission of thin metal filters which cover the pin-hole aperture. These filters transmit broad wavebands of radiation and cannot provide monochromatic images of the Sun in particular spectral line wave-lengths. A concave grating spectroheliograph has been used by Tousey<sup>4</sup> to record monochromatic solar images in certain strong emission line wave-lengths, but this technique cannot be used at short wave-lengths because of the low reflectance of normal incidence optics. The need for suitable techniques to record spectroheliograms at wave-lengths below 260 Å became evident after the observation of a group of intense emission lines at 170–220 Å in the solar spectrum<sup>5</sup>. These lines have recently been produced in plasma devices at Culham Laboratory and have been classified as allowed transitions in ionized iron FeVIII to FeXII (ref. 6). Information about the intensity distribution of these spectral line emissions on the solar disk would be a valuable aid to our understanding of the structure of the solar atmosphere.

An instrument which can be used to record monochromatic images in the wave-length region below 400 Å has recently been developed at Culham<sup>7</sup>. The imaging properties of a pin-hole camera are combined with the dispersion of a plane diffraction grating used at grazing incidence to form a compact extreme ultra-violet spectroheliograph. This instrument was flown for the first time on the stabilized *Skylark* rocket launched on April 9, 1965. A single exposure on Kodak Pathé 'SO-7' film was obtained during 250 sec of stabilized flight, the peak altitude being 160 km. The attitude control unit stabilized the nose cone within the extremes of  $\pm 3$  min of arc relative to the Sun.

Fig. 3 shows the extreme ultra-violet spectroheliograms together with a comparison photograph obtained with the same instrument viewing an ionized helium plasma in a laboratory discharge tube. The only important spectral lines produced by the helium plasma in this wave-length region are the first two members of the HeII Lyman

series at 304 Å and 256 Å. Monochromatic images of the discharge tube window can be seen at these wave-lengths. Two series of solar images are reproduced together with the helium comparison spectrum. These were obtained using two different sizes of pin-hole aperture each covered by thin aluminium filters to exclude visible light. The upper pin-hole was 0.75 mm diameter giving 10 min of arc resolution. The lower pin-hole was 0.25 mm diameter to give less exposure but a greater resolution of about 3 min of arc (about one-tenth of a solar diameter). The zero order image in the upper spectrum is over-exposed but the HeII 304 Å image is correctly exposed and shows only slight limb brightening on a uniformly emitting disk image. The image formed mainly by FeIX 171 Å radiation is best seen in the centre spectrum. Equatorial limb brightening is marked, but the emission from active spots is less obvious than in soft X-ray images obtained with a simple pin-hole camera in the same flight. Initial considerations indicate that the limb brightened emission between 60 Å and 150 Å is real.

The results described here were obtained by the combined efforts of several groups and individuals as listed in reference 1. We particularly thank the groups at the Royal Aircraft Establishment, Farnborough, Elliott Brothers of Frimley, W. R. E. Salisbury and our colleagues in the Natural Plasma Group at Culham for their participation.

## RADIO ASTRONOMY

### Spectrum of Low-frequency Radio Emission from NGC 1275

Two recent communications<sup>1,2</sup> have described an anomalous feature in the spectrum of the radio emission from the Seyfert galaxy NGC 1275 (3C84) (ref. 3) at frequencies above 3,000 Mc/s (Fig. 1). Between 178 Mc/s and 3,000 Mc/s, measured flux densities can be fitted with

a constant spectral index. At lower frequencies, measurements by Burke and Franklin<sup>4</sup> at 22.2 Mc/s and, more recently, by Erickson and Cronyn<sup>5</sup> at 26.3 Mc/s and by Williams<sup>6</sup> at 38 Mc/s, have given flux densities greater than would be predicted using this spectral index. This communication describes some preliminary results of observations at 10.03 Mc/s and 22.25 Mc/s made using the new pencil beam T-shaped arrays at the Dominion Radio Astrophysical Observatory. The observations at these frequencies also show excessive flux densities for the source.

The 22 Mc/s observations were made using a central portion of the final T now nearing completion. This smaller T measures 32λ east-west by 16λ north-south, giving a beam of 3.0° by 3.4° at the zenith. An absolute calibration of the system has not yet been attempted. The flux density scale has been calibrated with estimates for three sources; Virgo A, Hercules A, and 3C123, all of which appear to have a nearly constant

Fig. 3 Extreme ultra-violet spectroheliograms (*Skylark* SL 303, April 9, 1965)

Source	$S_m \times 10^{-26} \text{ W m}^{-2} (\text{c/s})^{-1}$	Probable error (P.E.)
Virgo A	5,900	$\pm 810$
Hercules A	5,330	$\pm 510$
3C123	835	$\pm 130$
NGC 1275	815	$\pm 155$

spectral index between 38 Mc/s and 1,000 Mc/s. Flux densities in this range were taken from a compilation by Kellerman<sup>7</sup> and fitted with least-squares parabolas to give estimates for each source at 22.25 Mc/s. Calibrations of the scale using the three sources have a root mean square variation about the adopted mean value of 10 per cent, or a probable error of the mean of about 5 per cent. Because of possible systematic errors in the flux densities used to derive these estimates an absolute accuracy of 15 per cent has been adopted for the calibration. Corrections for ionospheric absorption have been included, but are small, since most of the observations were made during the night.

The observations must be corrected for 'confusion' with 3C83.1, which is 30 min of arc from NGC 1275. This has been done using an estimate by Williams<sup>8</sup> of  $108 \times 10^{-26} \text{ W m}^{-2} (\text{c/s})^{-1}$  for the flux density of 3C83.1 at 22.25 Mc/s. The corrected flux density of NGC 1275 and the flux densities of the three standard sources determined using the adopted mean calibration are shown in Table 1.

The 10 Mc/s *T* measures 45λ east-west by 24λ north-south, giving a beam of 2.7° by 2.3° at the zenith. An absolute calibration of the system is not available at present and flux densities are measured relative to Virgo A. A linear extrapolation of measured values<sup>7</sup> yields a flux density of  $10,000 \times 10^{-26} \text{ W m}^{-2} (\text{c/s})^{-1}$  for Virgo A. This is in good agreement with a value based on computed antenna parameters and noise diode calibrations.

Ionospheric absorption, occurring mainly in the *F*-region, has been estimated from ionosonde data as 6 per cent and 27 per cent for the observations of Virgo A and NGC 1275, respectively (mean transit times at 0130 and 1815 L.T.). A correction for the 'confusing' source 3C83.1 has been made using an estimate by Williams<sup>8</sup> of  $173 \times 10^{-26} \text{ W m}^{-2} (\text{c/s})^{-1}$  for its flux density at 10 Mc/s.

The flux density obtained for NGC 1275 at 10.03 Mc/s is  $980 \pm 340$  (P.E.)  $\times 10^{-26} \text{ W m}^{-2} (\text{c/s})^{-1}$ . The major sources of error in this preliminary result are due to the effects of ionospheric scintillation and absorption.

The results are plotted as open circles in Fig. 1 together with a compilation of the results of other observers<sup>1,2,3,4</sup>. The points in the frequency interval 178 Mc/s to 3,000 Mc/s have been fitted with a straight line of slope  $-0.69$  and this has been extended as a dashed line to higher and lower frequencies. The remaining points have been fitted with a smooth solid curve.

Fig. 1. The radio spectrum of NGC 1275. The flux densities reported in this letter are shown as open circles

The results presented here confirm the existence of a low-frequency spectral component in the radio emission from NGC 1275. It has a spectrum with a slope of about  $-2.0$ , which becomes less steep at frequencies below 20 Mc/s. These observations do not yield any information on the accurate position and angular diameter of the source. Measures of these parameters would be of considerable value in any discussion of the nature of this low-frequency component.

The 10 Mc/s project is a joint undertaking with the Mullard Radio Astronomy Observatory, Cambridge.

## PHYSICS

### Spectrum of Laser Light Scattered from a Single Giant Pulse in a Laboratory Plasma

IN a previous communication<sup>1</sup> we reported the forward scattering of a laser beam in a 0-pinch plasma in which co-operative effects dominated the scattered spectrum.

The spectrum had been obtained from a number of separate shots; the Fabry-Perot etalon being adjusted after each shot to accept a different spectral element. These results suffered due to the lack of reproducibility of the laser from shot to shot as well as possible variation in the plasma properties of the discharge. Particularly damaging were the random shifts in the laser central frequency because of temperature variations as the ruby had to be refrigerated to obtain a sufficiently narrow spectral line breadth of the laser emission. As these random shifts were comparable with the spectral breadth of the ion peak itself the complete profile of the line could not be obtained.

To improve this situation a fourteen-channel photoelectric spectrum analyser was constructed using the Fabry-Perot etalon as the dispersing element. The basic operation of this type of instrument is described in another publication<sup>2</sup>.

Briefly, different portions of a Fabry-Perot fringe corresponding to different spectral resolution intervals are focused at various positions along the axis by an axicon or thin prism of revolution. An array of light guides placed along the axis conducts the light so focused to a series of photomultipliers. The number of channels is set equal to the finesse of the etalon which in our case was  $\sim 14$ .

In order to present the spectrum on a single oscilloscope, the photomultipliers were connected by lengths of 125-ohm cable so that the outputs of various channels were delayed 25 nsec with respect to each other. As the giant pulse of the laser was only 20 nsec long the signals of the different spectral channels were thus separated in time. The photomultipliers were matched to the cables by the use of two small inductances which with the anode capacitance of the photomultiplier formed a T-section with the same characteristic impedance as the cables. Reflexions were reduced to the level of the noise. One

Fig. 1. Above, oscillogram giving spectrum of laser alone; below, oscillogram giving spectrum of laser and plasma together

end of the cable was terminated and the other passed to the input of a Tektronix 517 A oscilloscope. The photomultipliers were RCA type 7285. Variations in sensitivity among the channels due to the attenuations of the delay cable, different transmissions of the light guides and variations in the sensitivities of the photomultipliers themselves were compensated by adjusting the voltages applied to the dynodes of the different tubes. Because the shot noise arising from the light emitted by the plasma would combine from the different channels to give a noise level  $(14)^{1/2}$  times larger than that of each channel alone if the photomultipliers were continuously active it was necessary to include an electro-optic shutter which would admit light to the analyser only during the time of the giant pulse. A Kerr cell was thus placed in the system immediately before the etalon and pulsed open for 50 nsec at the time of the giant pulse. Except for this Kerr cell and the multichannel spectral analyser the apparatus and experimental conditions were essentially as described in the first reference.

The free spectral range of the etalon was 0.78 Å, hence the spectral interval between channels was 0.056 Å. Fig. 1 shows the spectrum of the laser pulse alone and the spectrum of the light in the plasma. The difference in position of the laser pulse between the two shots is an example of the troublesome fluctuations in laser emission frequency that plagued our earlier work.

It will be noted that the present spectrum is consistent with our previous results in so far as the errors in the other permit comparison. The ion temperature computed from the present profile is ~50 eV. The spectrum shows some evidence of the 'shoulders' or weak maxima predicted by the theory. A slight asymmetry toward shorter wave-lengths is observed, but this effect is not as strong as it appeared in the previous report, as the low-frequency wing of the ion spectrum was completely obscured by the shot-to-shot fluctuations of the laser central frequency.

The profile of the ion spectrum corresponds most nearly to that for equal electron and ion temperatures.

Using the estimate of density obtained from the magnitude of the total scattered intensity the resulting value of  $\alpha$  is well in excess of unity.

We thank Prof. B. Brunelli, director of the Laboratorio Gas Ionizzati, and other staff members of the Laboratory for their advice. We also thank R. Marchetti for his assistance. One of us (J. K.) was a EURATOM Research-Fellow during 1961-63 when this work was initiated.

### Annealing Investigations In High Dose Graphite

AFTER irradiation, the electron microscope has been used to show that graphite contains a dense speckling attributed to interstitial aggregates<sup>1,2</sup>. This anneals into resolvable loops, and finally disappears between 1,700° and 2,000° C.

In the work recorded here, graphite crystals obtained from the Ticonderoga Lead Mines, New York State, have been cleaned in the usual manner and irradiated to a total nickel dose of  $5 \times 10^{18}$  n cm<sup>-2</sup> at 200° C. As received the crystals could not be cleaved into specimens suitable for transmission electron microscopy. After annealing at 2,500° C in a carbon tube furnace flushed with argon, the crystals were easily cleaved and were found to contain a high density of large loops about 1000 Å diameter, all sheared by a  $1/3 \langle 10\bar{1}0 \rangle$  displacement, and similar in appearance to those reported by Heerschap and Delavignette<sup>3</sup>. However, by tilting the foil to remove the ambiguity of the basal plane component of the Burgers vector, and observing the way the contrast changed from one side to the other of the dislocation line on tilting the specimen through small angles about a Bragg reflexion<sup>4</sup>, the loops were found to be of interstitial character.

A modified<sup>5</sup> specimen holder for the Philips EM 200 allowed a thin foil to be annealed in a furnace and a predetermined area to be re-examined. Hence it was possible to observe given loops after a series of 5 min anneals at 2,500° C and to measure their change in diameter with time.

It was found that all loops obeyed the equation<sup>6</sup>:

$$\frac{dr}{dt} = A \cdot \exp\left(-\frac{E}{kT}\right) \cdot \left[\frac{1}{r} - \frac{1}{\bar{r}}\right]$$

where  $A$  is a constant,  $E$  the energy of formation plus the energy of migration for the mobile point defects. Loops of radius  $r$  larger than a critical radius  $\bar{r}$  grew, and loops smaller than  $\bar{r}$  shrank. This is typical of a supersaturation controlled process. From a plot of  $dr/dt$  against  $r$  a value of 5.5 eV was obtained for  $E$ .

This result can only be taken as approximate at the moment because of assumptions made in evaluating the pre-exponential factor  $A$ . It is hoped to improve the accuracy by carrying out further isothermal anneals at different temperatures.

### Maximum Growth Rate of Rayleigh-Taylor Instabilities due to an Electromagnetic Force

INTEREST has recently been shown in Rayleigh-Taylor instabilities such as might affect the flow of a striated fluid in a magnetohydrodynamic-generator duct. In such situations there will be an electromagnetic force of value  $J \times B$ , where  $J$  is the electric-current density and  $B$  is the magnetic-field strength, in addition to forces due to gravity and acceleration of the fluid.

Lemaire<sup>1</sup> considered this problem, and showed first that the stability of a two-fluid interface for wave-fronts perpendicular to the current lines (Fig. 1) depends on the sign of  $dB/dx$ . If  $dB/dx < 0$  the situation is stable, if  $dB/dx = 0$  the situation is neutral, and if  $dB/dx > 0$  the situation is unstable. It should be pointed out that if  $J$  or  $B$  is reversed in direction so that the force is directed from the less-conducting fluid to the more-conducting fluid, these conditions are also reversed, giving the possibility of instability in this case also. The reason for this behaviour is that the total current passing under a trough or a crest of a wave is the same, and the distribution of the field vector will therefore determine whether the total force due to the  $J \times B$  terms is greater under a trough or a crest.

Lemaire goes on to consider the stability of the interface for wave-fronts parallel to the current lines. The results in this case when the field is uniform can also be obtained by adding a term in the analysis of Bellman and Pennington<sup>2</sup>, since the force is now of constant direction and magnitude and can be treated as a gravitational force in the analysis.

Prof. J. A. Shercliff suggested the idea of conducting an experiment to investigate these instabilities. A trough about 1 in.  $\times$  1 in.  $\times$  2 in. deep was set in a magnetic field and partly filled with mercury. The trough was designed so that the current could be passed through the mercury at right angles to both the field and the vertical. The deflexion of the surface was measured with a capacitance probe at the suggestion of Dr. H. Marsh. The probes, which were made at the laboratories, were used in conjunction with a Wayne Kerr meter and gave a full-scale deflexion for a gap of about 0.020 in. Tests were run to obtain the maximum growth rate of instabilities for various values of the  $J \times B$  force when directed upwards. Under the prevailing conditions of uniform field the instabilities should be two-dimensional, and this appeared to be confirmed as at just unstable conditions the mercury rose in a two-dimensional wave with the crest running

Fig. 1. Geometry of the problem

Fig. 2. Logarithmic plot of record of the growth of the instability for  $J \times B = 1.06 \times 10^4$  amp  $\times$  webers/m<sup>2</sup>

Fig. 3. Plot of experimental points obtained with 'Tufnol'-sided trough, with theoretical curve for comparison

from one electrode to the other and remained moderately stationary at a large deflexion. The maximum growth rate for these two-dimensional instabilities<sup>3</sup> for a mercury-air interface taking into account surface tension and neglecting viscosity, when modified to take account of the  $J \times B$  force, directed upwards, is:

$$n^2 = \frac{2}{3(3T)^{1/2}} \frac{(J \times B - g\rho)^{3/2}}{\rho} \text{ where } J \times B = |J| \times |B|$$

and the disturbance grows as  $\exp nt$ . In the foregoing equations  $g$  is the acceleration due to gravity,  $\rho$  is the density of the mercury,  $T$  is the surface tension at the mercury-air interface, and  $t$  is time.

The results obtained with a 'Tufnol'-sided trough are shown in Fig. 3. A logarithmic plot of a typical record of the growth of an instability is shown in Fig. 2. The uncertainty in some of the points in Fig. 3 is due to a decrease of slope with time on their logarithmic plots.

Further runs were performed with the trough lined with lead to alter the surface tension effects. In several of these traces the amplitude was found to vary very little before the trace disappeared due to the mercury making contact with the probe. The slopes, so far as they could be obtained from these records, all appeared to be low except for one in which the trace appeared similar to those obtained for Fig. 3. In this run the lead may have ceased to be effective.

The most likely explanation for the behaviour in this latter set of runs would seem to be that the lead lining sufficiently anchored the edges of the mercury that a whole number of wave-lengths was necessary to satisfy continuity, and hence at the mid-point of the trough there would have been a node and the probe situated at that point would have seen the surface changing in angle

only and not in height. This is to be contrasted with the case of 'Tufnol' sides in which the menisci would determine a symmetrical pattern of waves, and the lessened wetting of the side walls would remove the restriction on the number of wave-lengths.

When the force was acting downwards it was noticed that the mercury behaviour was extremely sensitive to anything which affected the uniformity of the current density. The insertion of any object obstructing the flow of current caused small fountains immediately next to it where the current density had fallen. The same effect was noticed when the mercury had not completely wetted the electrodes; particularly was this so in the trough corners.

Several fine colour photographs of this display were obtained; they show the characteristic bluish-white colour and band structure common to noctilucent clouds. These pictures appear to be the first photographic evidence of noctilucent clouds in the southern hemisphere. A black-and-white print of one of these is shown in Fig. 1.

Now that the existence of southern hemisphere noctilucent clouds has been proved, there are a number of questions relating to their characteristics remaining to be answered. Among these are their frequency of occurrence, spatial extent, height and velocity.

## GEOPHYSICS

### Noctilucent Clouds over Punta Arenas, Chile

As pointed out in a recent communication<sup>1</sup> the existence of noctilucent clouds in the southern hemisphere has long been in doubt.

The observational data from the northern hemisphere, showing a maximum in the month of July, suggest that, if noctilucent clouds also occur in the southern hemisphere, they should most likely be seen in the month of January.

In order to settle the question about the existence of noctilucent clouds in the southern hemisphere, I went to Punta Arenas, Chile (53°1' S, 71° N), for the period January 8-17, 1965, when the activity should be at its maximum. During this 9-day period, one night was overcast, one had broken and five had scattered tropospheric clouds, and two were completely clear. During the seven nights when noctilucent clouds could have been seen if they were present, only one display was observed. This was on the night of January 9-10, 1965. The display was moderate in intensity and extended up to about 8° above the horizon and in azimuth from about south-west to south-south-east. It was first observed at 2200 L.M.T. and was obscured from the observer's view by low tropospheric clouds at 2245 L.M.T.

Fig. 1

## GEOLOGY

### Early Metamorphic Complex of the Lewisian north-east of Gairloch, Ross-shire, Scotland

THE Lewisian of the Gairloch area has been recently divided<sup>1</sup> into an older *Ialltaig* and a younger *Gairloch* complex, the former tentatively equated with the Scourian<sup>2</sup> of the Assynt-Scourie region and the latter with the post-Scourian sequence (the 'Laxfordian' of Sutton and Watson<sup>3</sup>) of the Laxford area. More recently, the post-Scourian sequence of the Assynt-Scourie region has been shown to include two separate metamorphic episodes, at 2200 m.y. (Inverian) and 1600-1500 m.y. (Laxfordian *sensu stricto*)<sup>4</sup>. Preliminary dating of rocks from Gairloch<sup>4</sup> indicates that recrystallization of the early *Ialltaig* complex occurred in the period 1600-1500 m.y. and that this is probably the age of the main phase of metamorphism and deformation of the later Gairloch complex—that is, equivalent to the Laxfordian, *sensu stricto*, of the north.

Detailed structural work in the Tollie area lying between Gairloch and Loch Maree (Fig. 1), which will be the subject of a separate paper, has shown that a granulite-facies metamorphic complex antedates and is affected by the main tectonic phase (Laxfordian) of Gairloch. The Tollie area was first described by Clough<sup>5</sup>, and the structure explained in terms of an early complex of gneisses cut by basic dykes and affected by later deformation and metamorphism. Sutton<sup>6</sup> has criticized the validity of my interpretation of the chronology of the Gairloch area<sup>1</sup> on the grounds that it is inconsistent with Clough's observations at Tollie. However, detailed structural or petrological work relating to this area has not hitherto been published nor a precise correlation made with better known and dated sequences. The purpose of this paper is to summarize the evidence relating to the age of the early complex at Tollie and the correlation with the structural sequence at Gairloch.

It will suffice to state here that the Lewisian of the Tollie area is made up of a complex of gneisses comprising both basic and acid varieties cut by a large number of basic dykes, now amphibolite<sup>7</sup>. The most common type of gneiss is a quartz-plagioclase-K feldspar-biotite rock with epidote, sphene, apatite and ore. The biotite-gneiss is frequently interbanded with a hornblende variety. Basic and acid hornblende-gneisses predominate in the north-east.

Correlation with the Gairloch structural sequence. The main tectonic phase in the

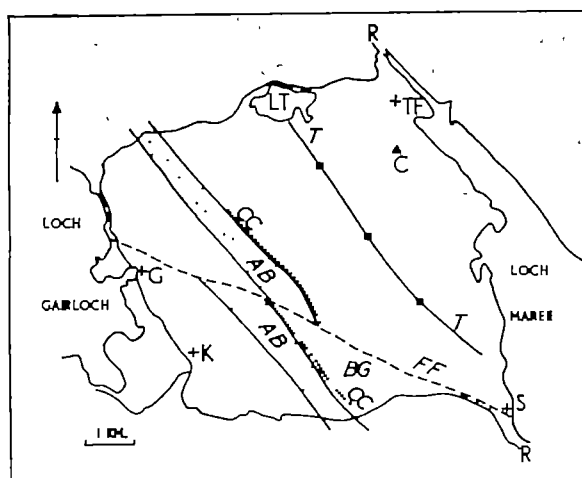

Fig. 1. Sketch map showing the location and certain geological features of the Tollie and Gairloch areas. G—Gairloch P.O.; LT—Loch Tollaigh; TF—Tollie Farm; C—Craig Mhor Thollaidh; S—Slattadale; K—Kerrydale; R-R—main road Poolawe-Gairloch-Achnasheen; T-T—trace of axial plane of Tollie antiform; AB—Aundray basite; BG—Buainichean gneisses; CC—Creag Bhan crush-belt; FF—Flowerdale fault.

Gairloch (post-Ialltaig) complex<sup>1</sup> is characterized by north-west-south-east steep or vertical foliation and strongly developed lineation with variable plunge. Folds are generally similar in style and have axial planes parallel or nearly parallel to the steep foliation. The main-phase deformation was accompanied by metamorphism of epidote-amphibolite facies in which both schists and gneisses were formed from the post-Ialltaig sediments.

The main-phase structure and metamorphism can be traced north-eastwards into the Tollie area where they are much more variably expressed. South-west of a north-west-south-east line through the west side of Loch Tollaigh (Fig. 1) the main-phase structure is indistinguishable from that of the Buainichean gneisses in the north-eastern part of the Gairloch area, but north-east of this line, along the crest and on the gently dipping north-east flank of an antiform (the 'Tollie antiform' of Clough<sup>2</sup>), the closely spaced steeply dipping main-phase foliation is replaced by a variably dipping, usually nearly horizontal foliation that is much less prominent, and the similar folds with steep axial planes are replaced by more open plastic folds with variably dipping axial planes (Fig. 2). The lineation, which is the dominant structural element and is parallel to the fold axes, corresponds to the intersection of the main-phase foliation  $S_M$  with the earlier gneissose banding  $S_G$  or to the intersection axis of variably dipping mica cleavages. On the south-west flank of the Tollie antiform,  $S_G$  is steeply dipping and becomes progressively obliterated and replaced by  $S_M$  in a south-westerly direction. On the crest of the Tollie antiform, and north-eastwards to Loch Maree,  $S_G$  is typically well developed and is modified rather than destroyed by the main-phase structure. The metamorphic fabric shows a corresponding variation across the area. In the eastern part, basic gneisses containing a relict granulite-facies mineral assemblage (plagioclase-hypersthene) are enclosed in the normal epidote-amphibolite-facies gneisses which are granoblastic with smoothly rounded, roughly equidimensional grains whose mean diameter is around 1 mm, the relict high-grade fabric being considerably coarser than 1 mm. In the central part of the area on the crest and north-east limb of the Tollie antiform, the mean grain-size is around 0.5 mm, but the fabric is otherwise similar to that in the east. On the south-western limb of the antiform, the fabric changes progressively and markedly. The mean grain-size decreases to around 0.1–0.2 mm; the grains are irregular in outline and vary considerably in size; large grains are frequently sutured and surrounded by smaller; lepidoblastic rather than granoblastic texture is pre-

dominant; and large quartz grains are strained. These differences are attributed to the effect of large-scale differential movement along the closely spaced foliation planes  $S_M$  during recrystallization on the flank of the antiform, contrasted with the comparatively static conditions in the crestal zone.

The pre-main-phase banding  $S_G$  is a coarse gneissose banding formed in a previous metamorphic episode that must, at least in parts, have reached granulite facies. The banding is very irregular in orientation and is affected by tight folds which are refolded by the main-phase folds (Fig. 2b). It is also cut by dykes which are themselves affected by the main-phase metamorphism, the main-phase lineation being represented in the dykes by hornblende alignment and by folded acid veins.

$S_G$  is affected by at least two sets of major folds (the Tollie antiform is a composite structure) which probably correspond to the two post-Ialltaig sets (early phase and early main phase) postulated in the Gairloch area. Late phase minor folds, pegmatites, and crush belts, similar to those in Gairloch<sup>1</sup> post-date the main-phase structures of the Tollie area.

**Age and significance of the early complex.** The Gairloch complex is considered to represent a series of sedimentary and basic igneous rocks younger than the granulite-facies Ialltaig complex which forms a small thrust-bounded wedge within the Gairloch rocks<sup>1</sup>.

If the early high-grade rocks of central and eastern Tollie are equivalent to the Ialltaig complex, as seems most likely, there must be a discontinuity (an unconformity, possibly tectonically obscured) between the rocks of the Gairloch complex and the Tollie gneisses. The nearest rocks that undoubtedly post-date the early high-grade metamorphism of the Tollie rocks are fine-grained schists on the north-east side of the thick Aundray basite (Fig. 1). The discontinuity thus must lie somewhere in the 1½ km-wide belt of gneisses separating these schists from rocks with definite early banding in the Tollie antiform. However, despite effectively continuous exposure, no change in the character of the gneisses can be detected within this belt—although such a change could well be completely obscured by the structural and metamorphic effects of the main tectonic phase. The most likely site for the required discontinuity is the line of the late-phase Creag Bhan crush-belt (Fig. 1) which lies within a zone of intense main-phase movement<sup>1</sup> at or near the schist-gneiss junction. This interpretation implies that the greater part of the Buainichean gneisses may be older than the Gairloch sediments. Although I previously grouped them with the sediments, I also suggested the possibility of these gneisses being much older than the adjacent rocks (ref. 1, p. 420).

Fig. 2(a). Schematic diagram representing the main-phase structure of the Tollie antiform, section normal to antiform axis, looking north-west. Continuous lines represent  $S_G$  affected by main-phase minor folds; short lines represent main-phase foliation  $S_M$ ; dots represent main-phase lineation. In zone A,  $S_G$  is unrecognizable; zone B shows  $S_G$  dragged into a near-vertical attitude and intersected by sub-parallel  $S_M$ ; lineation is subordinate; in zone C, lineation is predominant and  $S_M$  has no consistent attitude; in zone D, lineation is again predominant and  $S_M$  is sub-parallel to gently-dipping  $S_G$ .

Fig. 2(b). Specimen of biotite-gneiss from the north-east flank of the Tollie antiform showing an early fold  $F_0$  affected by main-phase folds  $F_M$  with variable axial planes. The biotite has a variable planar orientation with a strong intersection lineation normal to the plane of the diagram, its growth is clearly associated with the formation of  $F_M$  and post-dates  $F_0$ .

The most probable age of the early high-grade complex is Scourian. However, the nearest dated Scourian rocks are 30 miles distant across the Laxfordian strike, and no detailed structural work has been published for the intervening ground. Alternatively, the early complex could be Inverian in age, or could correspond to some other metamorphic episode as yet unrecorded.

### A New Carbonatite in the Legetet Hills, Kenya

As a result of recent laboratory examination of some specimens obtained while collecting rock-types in the Legetet area of the Kericho District of Nyanza Province, a new occurrence of carbonatite has been found. The outcrop, which is quarried for lime, is located 35° 15' 32" W, 0° 9' 7" S (first edition of the 1:50,000 sheet South A-36, F-1-NE). Later inspection of aerial photographs of the region suggests that the carbonatite forms a hill about 200 ft. high, and extends for about half a mile north from the above locality (Fig. 1).

The carbonatite was formerly thought to be equivalent to the Koru limestone of Miocene age, which forms the hill just west of the carbonatite and just north of Legetet (Fig. 1). The Koru limestone is itself problematic, since although it is interbedded with fossiliferous rocks<sup>1-3</sup>, some curious features have been recorded. Thus Pulfrey<sup>4</sup> gives its mineralogy as "calcite 85 per cent, hydrated iron oxides and manganese oxides (mainly iron) 9.5 per cent, apatite 3 per cent, silicates 2.5 per cent".

In a 1927 Survey report, Wayland<sup>5</sup> recognized two distinct limestones at Koru, a fossiliferous one, and underneath it an "apparently unstratified, essentially crystal-

line" grey limestone with "no trace of organic structures", which "does not display the characters one usually associates with the limestones of the archaean complexes". Wayland further mentions that the grey limestone "seems to contain about 2.5 per cent of calcium phosphate".

On this evidence, it seems possible that other parts of the Koru limestone may also turn out to be carbonatite.

Our own observations, which are restricted to the one locality examined, are that the Legetet carbonatite is a fine-grained dark-grey carbonatite (specimen U.1 which was mistaken in the field for a calcified volcanic tuff) cut by dyke-like bodies three to four feet wide of a creamy calcite rock with conspicuous octahedra of magnetite (specimen U.3). The carbonatite seems to pierce the tuffs of Tinderet which are Tertiary in age. The dyke-like bodies trend approximately north-east-south-west, which is similar to that of the nephelinitic and alnoitic dykes which locally cut the Tinderet tuffs and Koru limestone.

In thin section the grey carbonatite (specimen U.1) consists of small phenocrysts of twinned calcite, embedded in a matrix of anhedral calcite grains nearly all of which are coated with iron oxide. Occasional apatite and a few small wollastonite crystals occur. The rock is cut by a thin vein of a clear untwinned carbonate mineral with platy habit which proved, by X-ray powder photography, to be pure calcite.

The creamy carbonatite U.3 contains phenocrysts up to 4 mm long of a carbonate mineral. Staining techniques indicate that the matrix is pure calcite but the phenocrysts are slightly ferrous calcites. An examination of the rock in thin section indicates a mixture of two carbonatites. A coarse carbonatite rich in apatite and containing crystals of pyrochlore and cancrinite is invaded by a fine-grained carbonatite. The texture of the apatite suggests that it is being replaced by calcite. The phenocrysts in the fine-grained carbonatite appear to be derived from the coarser carbonatite.

Preliminary geochemical evidence from Mr. T. Deans of the Overseas Geological Surveys, London, suggests that specimens U.1 and U.3 contain amounts of strontium, barium, niobium and yttrium comparable to those found in other carbonatites, and in excess of those normally to be expected in sedimentary limestones.

That carbonatite should occur here is not surprising. The area lies on the south-west flanks of the Tertiary alkaline volcano of Tinderet described by Binge<sup>1</sup>. It is considered significant that these new outcrops and the fenitized rocks of Buru Hill, seven miles south-west of Legetet, as well as Tinderet itself should lie in the eastward extension of the Nyanza (formerly Kavirondo) rift-valley described by Shackleton<sup>2</sup>.

### METALLURGY

#### Distribution of Grain Size in Annealed Metals

MUCH consideration has been devoted to the statistical distribution of grain size in a well annealed metal, as examples of which the work of Smith and of Beck<sup>1</sup> may be cited who, however, did not give a formula to represent the distribution curve. Recently, Papadakis<sup>2</sup> has published a paper concerning the relation between the volume distribution of grain size and the distribution as revealed by surface examination, but the measurements considered do not suffice to provide the basis for a precise, experimentally confirmed law.

Fig. 1. Variation of  $n/n_{\max}$  with  $(D/D_0)^{1/2}$ .  $\times$ , magnesium at  $123^\circ\text{C}$ ;  $\bullet$ , zinc at  $22^\circ\text{C}$ ;  $\Delta$ , cadmium at  $35^\circ\text{C}$ ;  $+$ , cadmium at  $135^\circ\text{C}$ ;  $\circ$ , thallium at  $100^\circ\text{C}$ .

Our investigations have led us to believe that  $D^{1/2}$ , where  $D$  is the grain diameter, has a fundamental significance in problems of grain growth<sup>1</sup>. We have therefore been led to prepare distribution curves of  $n$  against  $D^{1/2}$ , where  $n$  is the number of grains for which  $D$  lies within a specified narrow limit. We have done this for the four close-packed hexagonal metals with which we have been working, namely, magnesium, zinc, cadmium and thallium, with specimens subject to long anneal at  $123^\circ$ ,  $22^\circ$ ,  $35^\circ$  and  $100^\circ\text{C}$ , respectively, and also with cadmium subject to long anneal at  $135^\circ\text{C}$ , for which the average grain diameter is about 6 times that for  $35^\circ\text{C}$ . The average grain size ranged from 125 grain/mm for magnesium to 4.8 for cadmium at  $135^\circ\text{C}$ .

If  $D$  is expressed in terms of the value for which  $n$  is a maximum and if this maximum is taken as the same in all cases, the points for  $n$  against  $D^{1/2}$  in all five cases lie on the same curve, as shown in Fig. 1. The curve in question is represented by:

$$n = n_{\max} e^{-\alpha^2(D/D_0)^{1/2} - 1}$$

where  $D_0$  is the value of  $D$  for which  $n$  has the maximum value  $n_{\max}$ .  $\alpha$  is a dimensionless constant, which has the value  $\pi$ . This constant measures the spread of the curve.

The number of grains measured was in each case about 1,000. We have shown, by successive etchings, that the grain size, as revealed by surface examination, is the same at all depths.

## Neutron Microradiography of a Cadmium-Tin Alloy

X-RAY microradiography investigation of the internal structure of various alloys is a complementary tool to standard metallography. However, for alloys containing two or more elements with similar X-ray absorption coefficients, X-ray microradiography becomes difficult if not impossible. In an attempt to find a transmission method which could be used in its place, it was decided to use neutrons instead of X-rays.

The sample chosen for inspection was made from a furnace-cooled cadmium-tin casting containing 29.25 per cent cadmium. The thickness of the sample was  $125\mu$ . Cadmium and tin were chosen because of the large difference in neutron absorption cross sections. This gives the cadmium-rich areas of the alloy much more absorption capacity. The cross section of cadmium is 2,500 barns and that of tin is 0.63 barns.

The irradiation facility was in the University of Missouri at Rolla. This reactor is a 'swimming pool' type generating an average flux of  $8 \times 10^{12}$  n/cm<sup>2</sup> sec at 10 kW. The neutrons passed through 5 ft. of graphite before they intersected the sample.

The method used for neutron microradiography was an adaptation of Beck's procedure. In this process the sample is placed on an indium sheet and irradiated by a monoenergetic, unidirectional flow of neutrons. After irradiation, the indium is removed and placed against the emulsion of a Kodak 'Metallographic' plate. The indium will then expose the plate principally with  $\beta$ -radiation.

Fig. 1 is a photomicrograph of the specimen at a magnification of 6 diameters. The light tin-rich grains are in a dark cadmium-rich matrix. There are two types of grains, spheroid and ellipsoid. However, the spheroid grains are arranged in a line such that at low magnification their appearance is that of ellipsoid grains. Fig. 2 is a photomicrograph of the specimen of approximately the same magnification as Fig. 4 ( $\times 1.5$ ). Fig. 3 is an actual size neutron microradiograph of the specimen. The tin-rich areas are light while those of the cadmium are dark. In this sample the elongated tin grains and those of cadmium are easily distinguishable. This tends to indicate that the negative could be enlarged as much as 10 diameters. Fig. 4 is a neutron microradiograph magnified 2.5 diameters.

The white area is an indication of a flaw in the sample. The ellipsoid grains of the alloy are easily distinguishable.

Fig. 1

Fig. 2

Fig. 3

Fig 4

There are dark and light areas which are not evident in the photomicrographs. We believe these to be high concentrations of cadmium and tin, respectively. This indicates that the alloy was not thoroughly mixed.

We thank the reactor staff at the University of Missouri at Rolla, and Nelson Beck of Argonne National Laboratory, for their help. We thank the Indium Company of America and the American Smelting and Refining Company for materials.

### Diffusion Creep in Polycrystalline Magnesium

LIGHTLY stressed polycrystalline metals may deform by the vacancy diffusion mechanism proposed by Nabarro<sup>1</sup> and Herring<sup>2</sup>. At high temperatures,  $\sim 0.8$  of the absolute melting temperature  $T_m$ , lattice self-diffusion is rapid and an appreciable diffusion creep may take place at a rate ( $\dot{\epsilon}$ ) given by<sup>3</sup>:

$$\dot{\epsilon} = \frac{B_1}{d^3} \frac{\Omega \sigma}{kT} D_l \quad (1)$$

where  $B_1$  is a constant,  $\sim 10$  for equiaxed polycrystals;  $\Omega$  the atomic volume of the material;  $\sigma$  the small applied stress;  $D_l$  the lattice self-diffusion coefficient;  $d$  the mean grain diameter; and  $kT$  has the usual meaning.

An equation for the contribution to diffusion creep by grain boundary self-diffusion (coefficient  $D_{gb}$ ) has been suggested by Coble<sup>4</sup>:

$$\dot{\epsilon} = \frac{B_2}{d^3} \frac{\Omega \sigma}{kT} \omega D_{gb} \quad (2)$$

where  $B_2$  is a constant,  $\sim 150$ ; and  $\omega$  is the grain boundary width.

As equation (2) has a stronger grain size dependence than equation (1) and the activation energy for grain boundary diffusion is smaller than that for lattice diffusion<sup>4</sup>, vacancy creep controlled by the grain boundary mechanism will be favoured by fine grain sizes and lower temperatures of deformation ( $\sim 0.6 T_m$ ).

This communication describes experiments which confirm that diffusion creep may be controlled by either the lattice or grain boundary mechanisms according to the test temperature. Magnesium was selected for these experiments since convincing metallographic evidence for creep has been obtained previously during

experiments on a magnesium alloy containing internal slip lines was observed on

the specimen surface and the marked stress dependence of the steady creep rate ( $\dot{\epsilon} \propto \sigma^3$ ) was typical of a dislocation climb process<sup>5</sup> in agreement with previous work<sup>6</sup>. Below this stress, however, and down to  $\sim 1.7 \times 10^6$  dynes/cm<sup>2</sup> no slip lines were observed, and the creep rate was a linear function of the stress. These creep rates agreed within a factor of two with those predicted from equation (1) using known values for  $\Omega = 2.32 \times 10^{-23}$  cm<sup>3</sup> and the lattice self-diffusion parameters<sup>7</sup> ( $D_l = 1.0$  cm<sup>2</sup>/sec,  $Q_l = 32.0$  kcal/mol). This must be considered good agreement in view of the approximations in the theoretical derivation of the value of  $B_1$ . In addition, at a stress of  $9.6 \times 10^6$  dynes/cm<sup>2</sup>,  $\dot{\epsilon} \propto 1/d^2$  for grains between 8 and  $40 \times 10^{-3}$  cm in diameter and direct determinations of the activation energy for creep by the temperature cycling technique<sup>18</sup> yielded values  $30.8 \pm 5.6$  kcal/mol at a stress of  $3.5 \times 10^6$  dynes/cm<sup>2</sup> and a temperature of  $412.5^\circ$  C. These results indicate that diffusion creep rates in magnesium at  $0.75 T_m$  follow equation (1) and are controlled by lattice self-diffusion.

In the second experiment, carried out at  $270^\circ$  C ( $0.59 T_m$ ) on specimens of  $\sim 5 \times 10^{-3}$  cm grain size,  $\dot{\epsilon} \propto \sigma^3$  for stresses in excess of  $2.8 \times 10^7$  dynes/cm<sup>2</sup> while at lower stresses  $\dot{\epsilon} \propto \sigma^1$ . Under these conditions of linear stress dependence the experimental rates were more than thirty times faster than those predicted from equation (1), suggesting the dominating importance of equation (2). In order to compare the experimental rates with equation (2), values for  $D_{gb}$  and  $\omega$  were required. Following work on zinc<sup>11</sup> and cadmium<sup>12</sup> we take for magnesium  $D_{gb} \sim 1.0$  cm<sup>2</sup>/sec with  $\omega \sim 5 \times 10^{-4}$  cm while the activation energy for grain boundary diffusion is  $Q_{gb} \sim 0.6 Q_l$ , giving  $Q_{gb} \sim 19.2$  kcal/mol. From equation (2)  $\dot{\epsilon}/\sigma = 3.5 \times 10^{-18}$  cm<sup>3</sup>/dyne sec at  $270^\circ$  C in good agreement with the experimental value of  $\dot{\epsilon}/\sigma \sim 8 \times 10^{-18}$  cm<sup>3</sup>/dyne sec. Some support is given to this calculation by direct determinations of  $Q_{gb}$  by the temperature cycling technique. Initial results are  $Q_{gb} = 20.0 \pm 1.9$  kcal/mol at  $6.9 \times 10^6$  dynes/cm<sup>2</sup> and  $285^\circ$  C, indicating control by the grain boundary mechanism.

The practical importance of vacancy creep in metals and alloys operating at high fractions of the melting temperature has been pointed out previously<sup>4</sup>. The foregoing results demonstrate, for the first time, that vacancy creep by a mechanism involving grain boundary diffusion can be of dominating importance in fine-grained metals stressed at lower temperatures ( $\sim 0.6 T_m$ ).

### CRYSTALLOGRAPHY

#### Growth of Single Crystals of $\text{Ba}(\text{B}_{0.33}\text{Ta}_{0.67})\text{O}_3$ Perovskite-type Compounds

A REVIEW of the literature revealed that a considerable effort has been expended in the past few years on investigations of a large number of new compounds with the general formula,  $A(\text{B}'_x\text{B}''_{1-x})\text{O}_3$ , where  $\text{B}'$  and  $\text{B}''$  are two different elements in the octahedrally co-ordinated cation

the nickel spectrum is of a type similar to that observed by Cotton and Bannister<sup>4</sup>, for the corresponding triphenylphosphine oxide-perchlorate complex.

The structure of the cobalt-perchlorate complex has been shown by X-ray analysis to correspond to a tetragonal pyramidal arrangement of the groups around the metal ion, with the cobalt slightly out of the plane formed by the four oxygen atoms of the arsine oxide groups and a perchlorate group co-ordinated in the fifth position about the cobalt atom<sup>5</sup>. The second perchlorate group is considered to be ionic. The infra-red data are therefore in agreement with such a structure. The presence of co-ordinated perchlorate groups has previously been suggested for certain compounds of copper and nickel<sup>6,7</sup>.

The magnetic properties of the perchlorate complexes are of interest in view of this stereochemical arrangement. For the Mn(II) complex the observed moment, 6.1 B.M. (although a little high), is of the order expected for a spin-free  $d^5$  configuration, as the ground term is an orbital singlet and hence  $\mu_{\text{eff}}$  should be essentially independent of the stereochemistry of the molecule. For the Cu(II) compound the observed moment, 1.85 B.M., is in the general range reported for copper(II) salts with a planar or octahedral arrangement. However, the magnetic properties of the cobalt(II) and nickel(II) complexes are particularly interesting. For the cobalt complex the moment is 5.5 B.M. and this corresponds more closely to that anticipated for an octahedral environment with an orbital triplet ground state ( $^4T_{1g}$ ). This is the first reported example of a five co-ordinate cobalt(II) with the spin-free configuration. For an octahedral environment the maximum moment anticipated is 5.3 B.M.; the observed value can be accounted for on the basis of a distortion from octahedral symmetry which can lead to an increase in the moment<sup>8</sup>. It would appear from the magnetic data that the presence of the perchlorate group has a very significant effect on the composition of the ground term of the cobalt ion, and the magnetism indicates a considerable deviation from a planar arrangement. For the nickel complex the moment is of the order reported for the corresponding triphenylphosphine oxide complex<sup>4</sup>, notably higher than that normally observed for an octahedral arrangement. We are now investigating the magnetic properties of these complexes over a temperature range.

\*Note added in proof. Prof. Saccoccini and his co-workers have recently reported (*J. Amer. Chem. Soc.*, 87, 2057 (1965)), the structure of another example of high spin five-co-ordinated Co(II) derivatives in which there is a square pyramidal arrangement of the attached donor atoms.

of manganese, iron, cobalt, nickel, copper and zinc. The magnetic properties of this series, together with their absorption spectra in the ultra-violet, visible and infra-red regions, are discussed by those authors. Since the structural implications of these physical properties were not entirely conclusive, we have undertaken a structure analysis of the cobalt compound by single crystal X-ray diffraction techniques.

Powder diffraction photographs show the several compounds to be isostructural and single crystal photographs of the cobalt complex show the crystals to be tetragonal, space group  $P4/n$ ,  $a = b = 16.33 \text{ \AA}$ ,  $c = 10.77 \text{ \AA}$ ; with  $\rho_{\text{obs}} = 1.52 \text{ g/cm}^3$ ,  $\rho_{\text{calc}} = 1.50 \text{ g/cm}^3$  for two formula units per unit cell. The structure was determined by three-dimensional sharpened Patterson methods and a series of observed and difference Fourier syntheses phased on an increasing number of atoms. Subsequent refinement of the atomic positional and thermal parameters was accomplished using an anisotropic least-squares procedure, the usual residual being 0.12 for the 1,100 independent reflexions.

The cobalt atom lies on a four-fold crystal axis: the co-ordination polyhedron is a distorted tetragonal pyramid consisting of four crystallographically equivalent oxygen atoms of the arsine groups and one oxygen atom of a perchlorate group. The cobalt atom is displaced from the plane of the oxygen atoms from the four equivalent arsine oxides by 0.32  $\text{\AA}$  towards the co-ordinated perchlorate. Moreover, the co-ordinated oxygen atom of the perchlorate does not lie directly above the cobalt atom but is displaced 0.72  $\text{\AA}$  to one side of the four-fold axis in such a way that the arsine oxide O—Co—(perchlorate)—O angles range from 85° to 95°. The chlorine atom of the  $\text{ClO}_4$  group does, however, lie on, or very nearly on, the four-fold axis through the cobalt. Since the perchlorate ion does not have  $C_4$  symmetry, there must be rotational disorder of this group in the crystal among four equivalent orientations. The perchlorate ion is tilted with respect to the four-fold axis so as to make the Co—O—Cl angle through the co-ordinated oxygen equal to 110°; the Co—O distance is 2.10  $\text{\AA}$  compared with 2.02  $\text{\AA}$  for the distance Co—OAsMePh<sub>3</sub>, the difference being statistically non-significant at the present stage of refinement.

The co-ordinated perchlorate ion is strictly tetrahedral within experimental error. The locations of the oxygen atoms have been determined only with some difficulty, since with the random occupation of four equivalent positions it is necessary to locate four sets of four peaks of two electrons each rather than one set of four peaks of eight electrons each. The standard errors of the structural parameters for these atoms are, therefore, high. It is nevertheless quite clear from our study of the observed and difference Fourier syntheses, as well as the observed and calculated structure factors, that the perchlorate ion is acting as a monodentate ligand. From similar considerations we conclude that there are no water molecules present, and in particular that the metal atom is not octahedrally co-ordinated.

The arsenic atoms are tetrahedrally surrounded by the oxygen, two phenyl and one methyl groups (Fig. 1) with As—O = 1.70  $\text{\AA}$ , As—O<sub>1</sub> = 1.95  $\text{\AA}$ , As—O<sub>2</sub> = 1.97  $\text{\AA}$ , and As—O<sub>3</sub> (methyl) = 1.90  $\text{\AA}$  (all  $\pm 0.05 \text{ \AA}$ ). The angles at the arsenic atom vary from 105° to 115° and the angle Co—O—As = 129°.

The second, crystallographically independent perchlorate group is uncoordinated and is located on a two-fold crystal axis in a 'large hole' in the lattice among the

Fig. 1

crystal examination shows the dinitrate compounds  $(\text{Co}(\text{Ph}_2\text{MeAsO})_2(\text{NO}_3)_2)$  to be virtually indistinguishable from the diperchlorate. The nitrate group does not have point symmetry consistent with the 4 crystal symmetry of the two-fold position but, like the perchlorate, does have point symmetry consistent with the half-occupied four-fold position on the 2 axis.

While recent conductometric<sup>1,2</sup> and infra-red investigations, both in these laboratories and elsewhere<sup>3,4</sup>, have provided evidence for perchlorate co-ordination, it is nevertheless often assumed that the perchlorate group has negligible co-ordinating power, and direct structural evidence for perchlorate co-ordination in this series of complexes is therefore of interest. The orientation of the co-ordinated group must result from some compromise between the high symmetry (4) of van der Waals interactions (principally with the methyl groups) and the requirement of appreciable overlap between the bonding orbitals of the oxygen and the axially symmetric metal orbital.

A detailed discussion of the bonding in this complex and the relation of its stereochemistry to that of other 5-co-ordinate metal ions (for example, nitroso (dimethyldithiocarbonato) cobalt<sup>5</sup>) will be given elsewhere, as will full details of the analysis and refinement.

### Conduction In Tantalum-doped Thorium Dioxide

As part of a search for conducting refractory oxides which can be heated directly from room temperature to temperatures in excess of  $2,000^\circ\text{C}$  by induced radio-frequency currents without the need for pre-heating arrangements, a study has been made of the behaviour of hot-pressed thorium dioxide doped with various amounts of tantalum pentoxide. These systems possess no apparent advantages in oxidizing atmospheres, but do exhibit striking properties when prepared in reducing conditions and operated in a neutral atmosphere.

Using the induction heated hot-pressing furnace described by Moore, Ubbelohde and Young<sup>1</sup>, pure  $\text{ThO}_2$  attained a density of only 92.9 per cent theoretical under 300 kg  $\text{cm}^{-2}$  at  $2,000^\circ\text{C}$ , though reagent grade  $\text{ThO}_2$  containing  $\sim 200$  p.p.m. of trivalent cations did densify at this temperature. The hot-pressing was done *in vacuo* using a tantalum-lined graphite susceptor, and under these conditions the product possessed a white, stoichiometric core with blackened outer regions, presumably containing free thorium. After intimate mixing with  $\text{Ta}_2\text{O}_5$ , hot pressing under these strongly reducing conditions resulted in ready densification with considerable grain growth at moderate temperatures. Densities are calculated assuming ideal solution.

Moles % $\text{Ta}_2\text{O}_5$	0.05	0.25	0.5	1.0	2.0	3.05	5.0
Hot-pressing temp. $^\circ\text{C}$	1,950	1,960	1,980	1,700	1,650	1,600	1,740
Density, % of theoretical	88.5	97.9	97.4	96.3	98.4	99.0	97.9

The materials so obtained ranged in colour from violet (0.5 per cent  $\text{Ta}_2\text{O}_5$ ) to black (5 per cent). It appeared that the outer layers were substoichiometric, thus measurements were made only on material sliced from the core. Electron probe microanalysis confirmed that the  $\text{Ta}_2\text{O}_5$ , which presumably had served as a liquid intermediate phase during the early stages of sintering, was in fact distributed uniformly throughout the sintered specimens and had not aggregated at grain boundaries. On heating in air at  $800^\circ\text{C}$  the colour of the reduced specimens discharged, giving a colourless translucent product. X-ray powder diffraction revealed no lattice parameter changes either in the oxidized or reduced forms, consistent with the small weight uptake on oxidation, which indicated that less than 1 per cent of the  $\text{Ta}^{3+}$  ions were reduced to  $\text{Ta}^{4+}$ . Barring evidence to the contrary, we assume that the tantalum is in solid solution, because it was found to be distributed uniformly in grains several hundred microns across in the product, even though the particle size of the starting materials was  $< 10\ \mu\text{m}$ .

Resistivity measurements were made by 4-point potentiometric methods using graphite current electrodes and platinum-5 per cent rhodium voltage probes at temperatures up to  $1,540^\circ\text{C}$ . In agreement with Rudolph<sup>2</sup>, oxidized material showed no useful decrease in resistivity, general agreement being achieved between d.c. and 50 kc/s. However, in the reduced condition the room temperature resistivity of the doped samples was found to have fallen by 6-10 orders of magnitude with respect to pure  $\text{ThO}_2$ . Representative values measured in argon are 3-15 ohm cm (5 moles per cent  $\text{Ta}_2\text{O}_5$ ), 3,000 ohm cm (0.25 mole per cent  $\text{Ta}_2\text{O}_5$ ). Irreproducibility between specimens originated from the extreme sensitivity of contact resistance to atmospheric oxidation rather than from variations in bulk properties. Thus all surfaces had to be prepared under oil, even light abrasion in air leading to the

mole per cent  $Ta_2O_5$  fell in one run from 2,850 ohm cm at 25° C to 670 ohm cm at 1,140° C for example, whereas the resistivity of a sample containing 1.0 mole per cent tantalum pentoxide fell from 24 to 18 ohm cm over the same temperature-interval. In later runs this latter sample reached bulk resistivities as low as 0.2 ohm cm. Such materials can be heated *in vacuo* to temperatures in excess of 2,000° C by a direct current of a few amperes, but cannot be heated by induction at 500 kc/s, though promising results have been obtained at 15 Mc/s.

The mechanism of conduction is at present obscure, though it appears to have an excitation energy of 0.05 eV. No magnetoresistance or Hall effect could be detected even at 17 kgauss. One accordingly presumes that a hopping process occurs.

### Fluorine Shielding in Diatomic Molecules and the Lamb Term

Alexakos and Cornwell<sup>1</sup> have recently measured the  $F^{19}$  shielding constant  $\sigma_{\text{HF}}$  in chlorine mono-fluoride, ClF, and they found that the shielding is greater in ClF than in  $F_2$ . Three values of  $F^{19}$  shielding constants in diatomic molecules are now available, and they are shown

Table 1

System Shielding constant	Shielding constants (p.p.m.)		Relative to $F_2$	
	$F_2$ 0	HF 625	$F_2$ 676	ClF 875

In Table 1 together with the value<sup>1</sup> for free  $F^-$ . This value is subject to some uncertainty, most measurements obtained in compounds of  $F^-$  being somewhat lower<sup>2</sup>. The correct value is unlikely to exceed that shown in Table 1.

The shielding constant  $\sigma$  is usually regarded as the sum of the Lamb term  $\sigma^L$  and the paramagnetic term  $\sigma^P$ , which are of opposite sign. Saika and Slichter<sup>3</sup> suggested that the results for  $F^-$ , HF, and  $F_2$  could be explained purely on the basis of variations in  $\sigma^P$ , which would be zero for  $F^-$  and increase with the increasing covalency of the bond  $F-X$ . This view seems to have become accepted<sup>4</sup>, but if it is correct, the shielding should be greater in  $F^-$  than in any other species. The new value for  $\sigma_{\text{HF}}$  directs attention to possible variations in  $\sigma^L$ . In fact Saika and Slichter obtained a value of 2,000 p.p.m. for  $\sigma^P$  in  $F_2$ , which must either be an overestimate or an indication that there is a significant variation in  $\sigma^L$ .

The possibility of variations in  $\sigma^L$  for  $F^{19}$  has been mentioned only to be dismissed<sup>4</sup>. The value of  $\sigma^L$  increases with an increase in the electron density near the nucleus. Apart from the electronegativity, there are two other causes of a variation in this electron density. The first of these is an increase with the number of electrons. Thus the values for  $\sigma^L$  given by Dickinson<sup>5</sup> show an increase from 18 p.p.m. in hydrogen to 464 p.p.m. in fluorine and 1,150 p.p.m. in chlorine. In a negative ion, however, the greater diffuseness of the orbitals compared to an atom tends to cancel out the increase with the number of electrons. Thus, Sidwell and Hurst's value<sup>6</sup> for  $\sigma^L$  in  $F^-$  is only 2 p.p.m. higher than their value for fluorine. The increase in  $\sigma^L$  with the number of electrons is also shown for molecules, although the calculated values may be less reliable than those for atoms. With Ransil's

functions<sup>7</sup>,  $\sigma^L$  for the proton<sup>8</sup> in HF is 78 p.p.m. higher than the accepted value<sup>9</sup> for  $H_2$ , and  $\sigma^L$  for  $F^{19}$  is 48 p.p.m. higher in  $F_2$  than in HF<sup>9</sup>.

The second effect is the increase in electron density at the nucleus on molecule formation. This effect is well known for hydrogen, but it is often neglected for other molecules. It leads to an increase in  $\sigma^L$  of 14 p.p.m. for  $H_2$ <sup>8</sup> compared to  $H^+$ , and 51 p.p.m. for  $F_2$ <sup>8</sup> compared to  $F^+$ .

Both these effects will contribute to a greater value for  $\sigma^L$  in ClF than in  $F^-$ , and the increase might well be 100 p.p.m. or more. Although this does not account for the whole of the anomaly pointed out above, it is too large a contribution to be neglected. An experimental value for the shielding in BrF would throw much light on the relative importance of the various factors. The whole question is discussed in more detail elsewhere<sup>10</sup>.

I am indebted to Dr. C. D. Cornwell for helpful discussions.

### Carbon Adsorbents with Molecular Sieve Properties

It has been found possible to obtain an adsorbent with typical molecular sieve properties by thermal processing of granulated carbonaceous material (prepared on the basis of pyrolysis of wood material at about 500° C) at 970–980° C in the atmosphere of gases preventing the oxidation of the carbon material. The adsorption of oxygen at –196° C occurs in its micropores, whereas nitrogen and argon are adsorbed at this temperature on the surface of transitional pores and macropores<sup>1</sup> only. The volume of micropores of this adsorbent is 0.15 cm<sup>3</sup>/g and the value of the specific surface of transitional pores and macropores is nearly 17 m<sup>2</sup>/g. Adsorption of nitrogen and argon is substantially increased by raising the temperature to –78° C. This effect is completely analogous to that observed in the adsorption of nitrogen on 'Zeolite NaA' (type 4A)<sup>2</sup>. At 20° C water vapour is adsorbed in the micropores of the adsorbent, whereas benzene vapour is adsorbed at this temperature only on the surface of transitional pores and macropores. The values of adsorption are presented in Table 1. From the adsorption data it is evident that the dimensions of openings of the micropores are close to 4 Å. The adsorbent may thus be considered the carbon analogy of the 'Zeolite NaA' (4A). The shape of the adsorption isotherm of water vapour is

Table 1. VALUES OF THE ADSORPTION OF GASES (m.moles/g) AT PRESSURES 15 AND 70 MM. MERCURY

Gas	Temperature °C	15 mm Hg	70 mm Hg

O <sub>2</sub>	–196	5.25	5.80
N <sub>2</sub>	–78	0.38	0.84
N <sub>2</sub>	–196	0.17	0.18
N <sub>2</sub>	–78	0.50	0.51
Ar	–196	0.10	0.12
Ar	–78	0.25	0.42
C <sub>2</sub> H <sub>6</sub>	20	0.00	0.12

characteristic for the system water-active charcoal<sup>1</sup>. The steep rise of the adsorption isotherm is observed in the region of relative pressures 0.4–0.5 and the isotherm reveals a typical hysteresis.

From the point of view of adsorption selectivity the carbon molecular sieves are comparable to the classical 'Zeolite' sieves. In some cases the selectivity is even better. The carbon molecular sieve prepared by thermal processing of 'Saran' charcoal at 1,750° C selectively adsorbs benzene from the benzene-cyclohexane mixture<sup>2</sup>. These hydrocarbons, according to Barrer<sup>4</sup>, belong to the same group of compounds separated by zeolites. Additional activation (by carbon dioxide) of the carbon molecular sieve prepared from the 'Saran' charcoal to a low burn-off (11 per cent) renders its microporous structure accessible for cyclohexane molecules<sup>1</sup>. It can therefore be concluded that the molecular sieve properties of carbon adsorbents on the basis of 'Saran' charcoal are caused by narrowing of the openings of micropores.

### Structures of Oxodiperoxo-1:10-phenanthrolinechromium(VI) and Diperoxoquo-ethylenediaminechromium(VI)hydrate

As a part of an investigation of the structures of peroxochromates<sup>1–4</sup>, peroxochromium complexes with ethylenediamine and 1:10-phenanthroline have been studied, and that of  $\alpha, \alpha'$ -bipyridyl is under investigation.

The structures of  $[\text{Cr}(\text{O}_2)_2(\text{C}_{10}\text{H}_8\text{N}_2)]$  and  $[\text{Cr}(\text{O}_2)_2(\text{H}_2\text{O})(\text{C}_4\text{H}_{10}\text{N}_2)](\text{H}_2\text{O})$  have been solved by three-dimensional Patterson and Fourier methods, and refined some least-squares cycles. The *R*-factor has dropped to 0.13 and 0.18 respectively.

The unit cell dimensions of  $[\text{Cr}(\text{O}_2)_2(\text{C}_{10}\text{H}_8\text{N}_2)]$  were determined from rotation and Weissenberg photographs, and were refined from Guinier photographs using  $\text{CuK}\alpha$  radiation. The unit cell is orthorhombic with 4 molecules in the cell and with  $a = 10.554$  Å,  $b = 8.857$  Å and  $c = 16.239$  Å. The systematically absent reflexions were  $0kl$  with  $k + 1 = 2n + 1$  and  $h0l$  with  $h = 2n + 1$ . This is characteristic for the space groups *Pnma* and *Pna2*. During the structure investigation it became obvious that a plausible structure could be obtained based on space group *Pnma*.

The investigation has revealed that chromium is co-ordinated to two peroxo groups, one oxide oxygen atom and to the two nitrogen atoms of the 1:10-phenanthroline molecule, the geometrical configuration of the co-ordinated atoms being a pentagonal bipyramid with the oxide oxygen and one nitrogen atom at the apices. The O—O distance is  $1.42 \pm 0.02$  Å and the Cr—O<sub>oxo</sub> distance is  $1.58 \pm 0.03$  Å, values which are close to those obtained for similar compounds (1–4). Table 1 gives the atomic positions at the present stage of the refinement.

The unit cell dimensions of  $[\text{Cr}(\text{O}_2)_2(\text{H}_2\text{O})(\text{C}_4\text{H}_{10}\text{N}_2)](\text{H}_2\text{O})$  were determined from rotation and Weissenberg photographs and were refined from Guinier photographs using  $\text{CuK}\alpha$  radiation. The orthorhombic unit cell contains 4 molecules and has the dimensions:  $a = 7.594$  Å,  $b = 12.258$  Å, and  $c = 8.168$  Å. The systematically absent

reflexions were  $0kl$  with  $k = 2n + 1$  and  $h0l$  with  $l = 2n + 1$ , which is characteristic for the space groups *Pbcm* and *Pbc2*.

As there are only 4 molecules in the unit cell and as it was supposed from other evidence that the molecules did not contain a mirror plane, the correct space group was thought to be *Pbc2*. The fractional co-ordinates of the atoms, based on this assumption, are at the present stage of the refinement those given in Table 2 (*R* = 0.176). During the structure investigation it soon became evident that all atoms except the two carbon atoms were situated at positions that fitted space group *Pbcm* equally well (within the limits of error). With the carbon atoms assumed to occupying positions 8c of *Pbcm* with only half the equivalent positions occupied (evidently this means that in half the unit cells C<sub>1</sub> is above and C<sub>2</sub> below the 'mirror' plane, while in the rest of the unit cells the reverse is true), refinement was undertaken and the *R*-value became 0.183 after six cycles, the parameters being those given in parenthesis in Table 2.

Table 2. PARAMETER VALUES FOR  $[\text{Cr}(\text{O}_2)_2(\text{H}_2\text{O})(\text{C}_4\text{H}_{10}\text{N}_2)](\text{H}_2\text{O})$   
Space group *Pbc2*, assumed. In parenthesis are given the values obtained by assuming *Pbcm* to be the correct space group with O<sub>1</sub> and O<sub>2</sub> in 8d, C<sub>1</sub> and C<sub>2</sub> in 8c (half-filled), O<sub>3</sub> in 4c and all the others in 4c

This molecule can also be described as being co-ordinated to five ligands, namely, to two peroxo groups, one water molecule and the two nitrogen atoms of one ethylenediamine molecule as co-ordinating groups. The geometrical arrangement of the co-ordinated atoms is a pentagonal bipyramid. The water molecules are involved in hydrogen bonding, one with one peroxidic oxygen atom of each of two neighbouring  $[\text{Cr}(\text{O}_2)_2(\text{H}_2\text{O})_n]$  molecules and the other with two peroxidic oxygen atoms of one neighbouring complex molecule, forming chains through the whole crystal. The O—O distances are  $1.44 \pm 0.04$  Å and  $1.46 \pm 0.04$  Å, the Cr—O<sub>water</sub> distance is  $2.04 \pm 0.02$  Å, and the hydrogen bonding distances O<sub>peroxo</sub>...H...O<sub>water</sub> are 2.69 Å, 2.86 Å, 2.72 Å and 2.72 Å.  $\angle \text{O}_{\text{peroxo}} \dots \text{O}_{\text{water}}$  are 102° and 107° respectively.

The refinement will be continued to convergence, and complete reports will be published elsewhere.

# BIOPHYSICS

## Comparison of Viscometric Behaviour of Suspensions of Polystyrene Latex and Human Blood Cells

THE viscosity of blood is a complex physical property determined by many factors. These factors include at least: (a) the physical characteristics of the blood cells (size, shape, deformability, etc.); (b) the concentration of the blood cells; (c) the composition of the plasma (especially the proteins) and the interactions between plasma and cells; (d) the shear rate. To examine the influence of cell shape and deformability on blood viscosity, we have compared, at low shear rates, the viscosities of suspensions of red blood cells and suspensions of rigid, spherical latex particles with diameters comparable to the major diameters of red cells in human blood. Polystyrene latex (Dow Chemical Co., Midland, Michigan) used for this purpose consisted of rigid spheres, with a mean diameter of  $9.2\mu$ , suspended in water with soap and stabilized with colloidal silica. Human red blood cells are biconcave disks with a mean major diameter of  $7.2\mu$  (ref. 1) and are deformable<sup>2-4</sup>. In the work recorded here, plasma was removed from human blood and the cells washed and suspended in a protein-free solution (Ringer's solution), thus eliminating the influence of plasma proteins on blood viscosity and making the cell suspensions more comparable to the latex suspensions. Because of the dependence of the viscosity of cell suspensions on cell concentration and shear rate<sup>5,6</sup>, viscosity measurements on cell suspensions and latex suspensions were made over a wide range of particle concentration and at shear rates varying from  $50 \text{ sec}^{-1}$  to  $0.02 \text{ sec}^{-1}$ .

The coaxial cylinder viscometer developed by Glinson, Dauwalter and Merrill<sup>7</sup> was used in these experiments. The outer specimen cylinder rests on a nitrogen-gas bearing set in the fields of an electromagnetic torque-sensing and torque-generating system. The torque-sensor is connected through a feedback amplifier system to the torque generator, producing torques of  $10^{-1}$ – $10^{+3}$  dyne-cm to prevent the specimen cylinder from rotating. The inner rotating cylinder is driven by motors, powered and controlled by tachometer and feedback amplifier systems (Servo-Tek Products Co., Hawthorne, New Jersey), through a gear train at any rate of  $10^{-2}$ – $82 \text{ r.p.m.}$  Shear rates were calculated from the rate of rotation of the inner cylinder and the annulus gap between the two cylinders, assuming uniform shear rate across the annulus. Viscosities were calculated from the quotient of the torque generated and the shear rate. Viscosities and shear rates calculated in this manner (without use of approximations to the unknown flow equations) are only approximate. Nevertheless, these approximate viscosities are useful in

describing the flow behaviour of these complex systems in a differential or quotient form, demonstrating graphically the large differences in flow behaviour among these suspensions.

Venous blood was drawn from healthy male subjects. Heparin was added to prevent clotting. Plasma was removed from the blood after centrifugation for 10 min at approximately  $10^4g$ , and the cells were washed three times with a modified Ringer's solution (NaCl 0.9 g, KCl 0.042 g, CaCl<sub>2</sub> 0.024 g, and NaHCO<sub>3</sub> 0.02 g per 100 ml. aqueous solution). Aliquots of cells were suspended in appropriate volumes of Ringer's solution to prepare series of samples with cell volume fractions ranging from 0 to 0.95.

The supplied latex suspension contained 0.435 volume fraction of polystyrene spheres. Sodium lauryl sulphate (1:200 in relation to the polystyrene content) was added to remove the protective colloid from the polystyrene particles. Samples with various volume fractions were prepared by the addition or removal of water. When the samples were mixed briefly without prolonged stirring (referred to as the unstirred samples), the particles were uniformly dispersed. Stirring gently for 30 min produced loose clusters involving some of the particles, while stirring for 4 h caused the latex particles to form compact clusters containing most of the particles (Fig. 1).

The stirring of the latex suspensions caused dramatic changes in viscometric behaviour. Fig. 2 shows the relation between viscosity and shear rate for three samples of latex suspensions (unstirred, stirred for 30 min, and stirred for 4 h), as well as for Ringer suspension of human blood cells, all at volume fraction of 0.435. The unstirred latex suspension shows a dilatant behaviour, that is, the viscosity decreases as the shear rate is reduced. The latex suspension stirred for 30 min becomes mildly thixotropic, that is, the viscosity increases as the shear rate is reduced below  $1 \text{ sec}^{-1}$ . The latex suspension stirred for 4 h shows increased thixotropy. As already pointed out here, stirring of latex suspensions causes marked changes in the state of aggregation of the particles (Fig. 1). Since the uniform monodispersion of latex particles in the unstirred suspension is associated with a dilatant behaviour, and the formation of clusters in the stirred suspensions is accompanied by a thixotropic behaviour, it seems that the appearance of thixotropy in the latex suspensions is the result of cluster formation. This explanation is in agreement with the finding that heparinized whole blood, with the presence of many aggregates and plasma-cell interactions, has a more pronounced thixotropic behaviour than cell suspensions in Ringer's solution<sup>5,6</sup> in which the cells are largely monodispersed.

The viscosities of the latex suspensions, whether stirred or not, are considerably higher than those found for the cell suspensions (Fig. 2). The difference in viscosity

Fig. 1. Photomicrographs of diluted latex suspensions

Fig. 2. Logarithmic plot of viscosity versus shear rate for latex suspensions and cell suspensions, all with a volume fraction of 0.436 at 37° C

Fig. 3. Semilogarithmic plot of viscosity versus volume fraction of suspended particles for latex suspensions and cell suspensions at a shear rate of 0.05 sec<sup>-1</sup> at 37° C

between these two forms of suspension is especially marked at high particle concentrations. In Fig. 3, the log of viscosity at a fixed shear rate (0.05 sec<sup>-1</sup>) is plotted against the volume fraction of the suspended particles. At volume fractions below 0.3, the curves for unstirred latex and cell suspensions are essentially the same, whereas the stirred latex has a slightly higher viscosity. Above a volume fraction of 0.3, the viscosity of the latex suspensions increases sharply with rising particle concentration and becomes markedly higher than that of the cell suspensions. With particle concentration higher than 0.47, the viscosity of the latex suspensions becomes so high that the torque generated is above the limit of our instrument. As shown in Fig. 3, the viscosity of the latex suspensions rises sharply toward infinity. On the other hand, the viscosity of a cell suspension with a volume fraction as high as 0.95 is still within limits of the instrument and can be readily determined.

These results reveal striking differences in the viscometric behaviour between suspensions of rigid spherical particles (polystyrene latex) and those of deformable biconcave particles (red cells). We believe that these contrasting viscosity behaviours are evidence for the widely held idea that the ability of blood to flow at very high cell fractions depends on the deformability, and probably on the shape, of the cells.

We thank Dr. Ralph M. Wiley and Dr. Turner Alfrey, of the Dow Chemical Company, Midland, Michigan, for supplying the polystyrene latex, and Walter Logan, of the Bell Telephone Laboratories, Inc., for major contributions to design of the drive systems for the viscometers.

The experimental work reported here was carried out in the Laboratory of Hemorheology at Columbia University under U.S. Army contract DA-49-193-MD-2272 and was supported by several private donors, including the Mary Evelyn Townsend Fund, the Brook Foundation, Mrs. George W. Perkins, Mrs. Onolee Coffey and Mrs. Alan M. Scaife.

## Conformation of Acetylcholine

THE development of the attenuated total reflexion (ATR) method<sup>1,2</sup> for the examination of aqueous solutions in the infra-red region has made it possible to re-examine the problem of the conformation of acetylcholine (ACh) in aqueous and mammalian Ringer solution.

In the published crystal structure of ACh bromide, Sorum<sup>3</sup> postulated the simultaneous existence of two types of ACh chains: the extended and the ring planar; the latter form had an N<sup>+</sup> - - - alkyl and carbonyl oxygen distances of 3.51 and 5.32 Å respectively.

Three years later, on the basis of the infra-red study of ACh chloride dissolved in ethanol, it was suggested<sup>4</sup>, from the higher frequency of the carbonyl group ( $\nu_{C=O}$ ) in ACh than in ethyl acetate (I), that the former compound had a cyclic structure (II). The free base 2-dimethylaminoethyl acetate showed two  $\nu_{C=O}$  bands at 1,748 and 1,728 cm<sup>-1</sup> as did (I). In a later account the same authors<sup>5</sup> rejected the cyclic structure and suggested that there was an inductive effect from the quaternary nitrogen atom which would influence the carbonyl frequency.

(I)

(II)

The arguments presented<sup>4</sup> to account for the higher frequency of the carbonyl group in terms of the inductive effect of the quaternary nitrogen atom are unsatisfactory. It has been shown (ref. 6, and unpublished work by E. F. M.) that the mesomeric and/or inductometric interaction between the alkoxy and the acyl groups are negligible, that is, the contribution from (III) is not expected to be important. Further, in Fellman and Fujita's paper<sup>4</sup> the  $\nu_{C=O}$  of methyl and substituted methyl acetates,  $CH_3CO_2X$ , where  $X = Me$ ,  $-CH_2CN$  and  $-CH_2CO_2Et$ , are within the range  $1,758 \pm 4 \text{ cm}^{-1}$  and similarly those of ethyl and substituted ethyl acetates  $CH_3CO_2CH_2X$ ,  $X = Me$ ,  $-CH_2NO_2$ ,  $-CH_2N^+Me_3$ ,  $-CH_2N^+(Pr)_3$ , and  $CH_2N^+(Bu)_3$ , are within the range  $1,754 \pm 6 \text{ cm}^{-1}$ . (See Tables 2 and 3 of ref. 5):

The presence of a group exhibiting a strong  $-E$  effect, namely, nitro, cyano or carbethoxy, does not appreciably decrease the carbonyl frequency. If the cyclic structure (II) was predominant it would be expected that the carbonyl frequency would be decreased due to the increased polarization of the  $(C=O)$  group on bonding; for example, in co-ordination studies it has been clearly demonstrated<sup>7-9</sup> that if the carbonyl oxygen acts as a donor atom it results in a decreased  $\nu_{C=O}$ . However, since the spectra were recorded<sup>4,5</sup> in ethanol, there was the possibility of intermolecular hydrogen binding occurring (IV), which would not be expected to compete with (II) if this latter was present, but would give rise to lower frequency carbonyl bands in other esters investigated.

In the present work, although the spectra of ethyl acetate and of Ach chloride and bromide have been recorded in ethanol solution by transmission, the majority of the spectra have been recorded in water solution by reflexion using the ATR method<sup>1,2</sup>. This method was especially chosen since in reflexion water is remarkably transparent and thus we have also been able to record the spectra of Ach in mammalian Ringer's solution (a medium approximating more closely to those found *in vivo*). The frequencies of Ach chloride in ethanol solution obtained in reflexion ( $1,748 \text{ cm}^{-1}$ ) and in transmission ( $1,751 \text{ cm}^{-1}$ ) are in fair agreement, but this latter value is lower than that given by Fellman and Fujita<sup>4,5</sup> (namely,  $1,760 \text{ cm}^{-1}$ ).

The effect of solvent on the carbonyl frequency of Ach has been investigated in ATR, and since the frequencies are dependent on solvent it would suggest that hydrogen bonding is predominant; this is further confirmed, as examining ethyl acetate and Ach chloride and bromide under high resolution in ethanol by transmission shows that the carbonyl bands are multiplets (Table 2) presumably corresponding to different associated forms.

From Table 1 it is clear that the carbonyl frequency of Ach is of the order expected for aliphatic esters, and since the frequency is so dependent on the nature of the solvent the cyclic structure previously suggested<sup>4</sup> is not in agreement with the experimental evidence.

Ring structures do, however, exist in the crystalline state, the electrostatic interaction being between the  $N^+$  quaternary group and the alkyl oxygen, and not the acyl oxygen.

Table 1. CARBONYL FREQUENCIES OF ACH CHLORIDE IN DIFFERENT SOLVENTS —ATR METHOD

Solvent	$\nu_{C=O} (\text{cm}^{-1})$	Dielectric constant
MeOH	1,742	35.4/13°
EtOH	1,748	28.0/14°
EtOH: water (1:1)	1,753	—
Water	1,757	81.0
Ringer's solution	1,757	—

Table 2. CARBONYL FREQUENCIES OF ETHYL ACETATE AND ACH CHLORIDE IN ETHANOL SOLUTION (IN TRANSMISSION)

Ethyl acetate	Acetylcholine chloride	Acetylcholine bromide
1,745	1,751	1,754
1,750	1,748 (sh)	1,743
1,719 (sh)	1,742	1,737
	1,730	

The correctness of the foregoing interpretation is especially shown in the X-ray crystal structure<sup>10</sup> of muscarine iodide (V) where the  $N^+ \cdots$  ring ether oxygen distance, calculated with the published atomic co-ordinates, is only  $3.07 \text{ \AA}$ .

The van der Waals radius of oxygen being  $1.4 \text{ \AA}$ , this distance of  $3.07 \text{ \AA}$  has great significance as compared with the  $N^+ \cdots Cl^-$ ,  $N^+ \cdots Br^-$  and  $N^+ \cdots I^-$  distances of  $4.38$ ,  $4.37$  and  $4.56 \text{ \AA}$  calculated from the published atomic co-ordinates of the X-ray crystal structures of the tetramethylammonium halides<sup>11,12</sup>. Similarly, in muscarine and pentamethonium iodides<sup>13</sup> the closest  $N^+ \cdots I^-$  distances are  $4.49 \text{ \AA}$  and  $4.43 \pm 0.14 \text{ \AA}$  respectively.

The ATR spectra were recorded using a Research and Industrial Instrument Co. 'T.R.-3' unit with  $KR 5$  prism, but the prism holder and cell were gold plated to prevent attack of the metal by acids liberated during hydrolysis; a Perkin Elmer '137' spectrometer was used. The transmission spectra were recorded using a Grubb Parsons 'Spectromaster'. The ATR spectra will be submitted to *Documentation of Molecular Spectroscopy*.

Thanks are due to Mr. G. Y. Ahliah for assistance with the infra-red reflexion measurements.

## BIOCHEMISTRY

### Crystallization of Arginase from Normal and Cirrhotic Human Liver

It has been demonstrated that patients with liver disorders are particularly susceptible to ammonia intoxication<sup>1</sup>. Since ammonia is detoxified by urea synthesis, study of the enzymes of the Krebs-Hensleit cycle in the

normal and abnormal liver might provide useful information. Decrease of liver arginase activity in patients suffering from cirrhosis and hepatic coma has been reported by Ugarte, Pino and Valenzuela<sup>3</sup>. In our study, arginase was crystallized from a 'normal' human and a cirrhotic human liver and the catalytic efficiency of the enzymes from the two sources was compared.

Liver samples were obtained within 12 h of death and preparation of the acetone powder was begun immediately. The purification procedure was that developed by Bach and Killip<sup>4</sup>. A unit of enzyme is defined as that amount which would catalyze the production of 1  $\mu$ mole of urea in 1 min at 25° C, pH 9.5, at an arginine concentration of 0.285 molar<sup>4</sup>. Protein was estimated by the following formula<sup>5</sup>: protein concentration in mg/ml. =  $(OD_{280\text{nm}} - OD_{280\text{nm}}) \times F$ , where  $F$  is a dilution factor. Extraction of the acetone powder yielded 38.8 g of protein from the normal liver and 21.4 g of protein from the cirrhotic liver. The arginase activities of the solutions were 0.515 and 0.466 units/mg, the normal being the higher.

The analysis of the normal liver homogenate revealed that under our conditions of assay 13.0 units of enzyme were present per g of wet tissue. In the case of the cirrhotic liver 7.5 units of enzyme per g wet tissue were found. This represents specific activities of 0.013 unit/mg and 0.008 unit/mg respectively.

The specific activity of the crystalline enzyme from the normal liver approached 150 units per mg, and that from the cirrhotic 80 units per mg of liver protein.

The results indicate that the enzyme in the cirrhotic liver is either: (a) partially inactivated; (b) absolutely reduced in amount; (c) a less efficient catalyst; or (d) is more susceptible to denaturing agents than the normal and thus loses activity in the isolation procedure. Whatever the mechanism an apparent difference exists between the enzymes crystallized from the two sources. Cellulose acetate electrophoresis (Barbital buffer, ionic strength 0.1 M, pH 8.6) showed that the enzyme from both sources migrated in a single band.

The subjects, aged 53 and 74 years, both died of heart failure. The cirrhotic, who was the older, had a history of moderate diabetes mellitus for ten years and at the time of autopsy appeared slightly malnourished. In the case of the 'normal' patient, no other factors influencing liver function were apparent. Definite conclusions must await further investigation.

### Use of Light-scattering to Measure the Selective Interaction of a Macromolecular Solute with the Components of a Binary Solvent

A SOLUTION of a non-diffusible solute will in general contain the components of a mixed solvent in proportions different from those of an equilibrium diffusate, owing to non-ideal interactions between the solute and the solvent components. The distribution can be measured refractometrically<sup>1,2</sup> and can be expressed unambiguously for a binary solvent as the excess quantity of one of the solvent components (arbitrarily chosen) relative to unit quantity of the other, per unit quantity of solute. Direct refractometric measurement requires preparation of an equilibrium diffusate, and is limited with respect to the concentration of the solute by the sensitivity of the measurement. The use of diffusate can be avoided by measurement of

light-scattering, which also allows measurements to be extrapolated reliably to zero concentration of solute.

Casassa and Eisenberg<sup>1,2</sup> have shown that the excess scattering at zero angle  $\Delta R(0)$  of the macromolecular solute is expressed by:

$$k \frac{(dn/dc_2)c_2}{\Delta R(0)} = \frac{1}{M_2} + \frac{Bc_2}{M_2^2} \quad (1)$$

provided that: (1) the specific refractive increment of the solute  $(dn/dc_2)$  is measured against diffusate; (2) the scattering of diffusate is used in arriving at  $\Delta R(0)$ ; ( $k$  is constant;  $c_2$ ,  $M_2$  are the concentration and weight-average molecular weight of the solute and  $B$  the second virial coefficient). Conventionally equation (1) is used to determine  $M_2$  by measurement of  $(dn/dc_2)$ ,  $c_2$  and  $\Delta R(0)$ ; however, it may be used alternatively to measure  $(dn/dc_2)$  if  $M_2$  is known.

Consider a macromolecular solute (3) in a solvent consisting of a component (1) to which a second component (2) may be added.  $M_2$  is first measured by light-scattering of solutions of 3 in 1,  $(dn/dc_2)_1$  being measured refractometrically. Next, light-scattering measurements are made on a series of concentrations of 3 in a constant mixture of 1 and 2. Provided that the presence of 2 does not cause aggregation or disaggregation of 3, the value of  $M_2$  is unaffected.  $\Delta R(0)$  is obtained by subtracting the scattering of the solvent from that of solution, and the results are extrapolated to zero  $c_2$  in the usual way. Now, although these values of  $\Delta R(0)$  will be incorrect at finite  $c_2$ , they approach the correct value at zero  $c_2$ , since the compositions of solvent and diffusate then become identical; also at zero  $c_2$ , the term containing  $B$  vanishes (since a solute behaves ideally at zero concentration even if it reacts selectively with the components of a mixed solvent<sup>3</sup>) and equation (1) becomes:

$$\frac{L\lambda}{c_2 \rightarrow 0} k \frac{(dn/dc_2)c_2}{\Delta R(0)} = \frac{1}{M_2} \quad (2)$$

The value of  $(dn/dc_2)$  obtained is that which would be given by the difference of refractive index  $\Delta n$  of solution and diffusate at zero concentration of solute.

This value, which may be written  $(dn/dc_2)_{12}$ , is related to the excess quantity  $\alpha_2$  of (say) component 2 which is associated with unit quantity of component 3, since:

$$\frac{L\lambda}{c_2 \rightarrow 0} \Delta n = (dn/dc_2)_{12}c_2 + \alpha_2 c_2 (dn/dc_2)_1 \quad (3)$$

and:

$$(dn/dc_2)_{12} = \frac{L\lambda}{c_2 \rightarrow 0} \Delta n/c_2 = (dn/dc_2)_1 + \alpha_2 (dn/dc_2)_1 \quad (4)$$

where  $(dn/dc_2)_1$  is the specific refractive increment of 3 in 1.

In general  $\alpha_2$  is a function of  $c_2$  and may be positive or negative according as component 2 is 'bound' or 'excluded'<sup>4</sup> by component 3. For example, if 3 and 2 form a reversible stoichiometric complex, with dissociation constant  $K$  (expressed in molar terms), at  $c_2 = 0$  the degree of association  $\beta$  is given by:

$$K = \frac{(1 - \beta) 1000c_2}{\beta M_2} \quad (5)$$

and:

$$\beta = M_2/\alpha_2 \quad (6)$$

so that equations (4), (5) and (6) may be used to determine  $K$ . Again, if component 2 is 'excluded' by 3 (for example, a protein by hyaluronic acid<sup>5</sup>) from a volume  $\epsilon$  ml./g of 3, then:

$$\alpha_2 = -\epsilon c_2$$

The effect of adding a second solvent component on the excess scattering depends on the sign of  $\alpha_2(dn/dc_2)_1$ . If this is positive and increases with  $c_2$ , the excess scattering increases. If, however, it becomes increasingly negative with increase of  $c_2$ , the value of  $(dn/dc_2)_{12}$  and the excess scattering will at first decrease to zero, and

then increase again, provided that the solute is homogeneous with respect to  $(dn/dc)_1$  and  $\alpha_1$ ; if the solute is heterogeneous in either respect, a non-zero minimum of the excess scattering will be reached.

We have used this method to measure the selective interaction (in this case, exclusion) of hyaluronic acid (component 3) with bovine serum albumin (component 2) and have obtained results that agree with partition measurements<sup>6</sup> and with osmotic measurements<sup>7</sup>.

Phosphorylase a/b Ratio In the Lamprey Heart

CYCLOSTOME branchial hearts are known to contain large amounts of endogenous catecholamines<sup>1</sup> and to be markedly insensitive to added adrenaline<sup>2,3</sup>. There is considerable evidence to suggest that the process whereby the sympathomimetic amines normally enhance the force of cardiac contraction involves the transformation of the enzyme phosphorylase from the b to the a form<sup>4,5</sup>. The lack of sensitivity of cyclostome hearts to added adrenaline or noradrenaline might therefore be due to the endogenous amines having already activated the conversion of the phosphorylase enzyme from the b to the a form so that even in the absence of any added adrenaline or noradrenaline the enzyme phosphorylase would exist mainly in the a form. This possibility was investigated using hearts isolated from freshly decapitated lampreys (*Mordacia*). After five minutes immersion in aerated (95 per cent O<sub>2</sub> + 5 per cent CO<sub>2</sub>) modified Ringer solution<sup>6</sup> at 22° C, under which conditions isolated hearts will beat spontaneously for many hours, the hearts were rapidly frozen and the phosphorylase activity determined as described previously<sup>7</sup>, using tissue dilutions of 1/150 (w/v) and rabbit liver glycogen (Nutritional Biochem. Lab.) which had been purified as described by Krebs *et al.*<sup>8</sup>. The reaction mixture was incubated at 25° C.

Typical results are displayed in Table 1 where it is shown that approximately half the phosphorylase enzyme present in lamprey hearts is in the a form. Comparison of these results with those obtained from other similar experiments in which freshly isolated toad (*Bufo marinus*) hearts were used indicates that the percentage of the enzyme phosphorylase in the a form is approximately the same in toad and lamprey hearts. These results are summarized in Table 1. Lamprey hearts are known to contain approximately 50 µg catecholamines per g<sup>9</sup>; toad hearts contain approximately 1.25–1.6 µg/g<sup>9</sup>. It therefore seems unlikely that the endogenous catecholamines of lamprey hearts participate to any marked extent in the natural regulation of the percentage of the enzyme phosphorylase which is present in the a form.

Perfusion of isolated toad hearts with Ringer solution containing 4 µg/ml. adrenaline ('Hermette', D. Bull and Co.) or noradrenaline ('Levophed', Winthrop Laboratories) produces a marked positive inotropic and chronotropic response. The data summarized in Table 1 indicate that these inotropic and chronotropic changes are accompanied by the conversion of almost all the phosphorylase enzyme to the a form. These same concentrations of adrenaline and noradrenaline failed to produce either a chronotropic

Table 1. PERCENTAGE OF PHOSPHORYLASE ENZYME PRESENT IN THE 'a' FORM IN ISOLATED LAMPREY AND TOAD HEARTS

Experiment	Lamprey % a Inotropic <sup>5</sup> action	Toad % a Inotropic <sup>5</sup> action
Control	53 54 57 55	58 62 55 63
Adrenaline 4 × 10 <sup>-4</sup>	60 62	88 96 ++++ ++++
Adrenaline 1 × 10 <sup>-4</sup>	83 86	96 96 ++++ ++++
Noradrenaline 4 × 10 <sup>-4</sup>	46 48	85 92 ++++ ++++
Noradrenaline 4 × 10 <sup>-4</sup>	61 62	98 98 ++++ ++++
Isoprenaline 4 × 10 <sup>-4</sup>	90 95	100 95 ++++ ++++
Isoprenaline 5 × 10 <sup>-4</sup>	92 92	+++ +++

Where '-' denotes the absence of inotropic activity; '+' denotes an arbitrary unit of positive inotropic activity. Results of individual experiments are shown.

or inotropic response from isolated lamprey hearts. Table 1 shows that 4 µg/ml. of either adrenaline or noradrenaline did not produce any marked change in the percentage of the phosphorylase enzyme which was present in the a form in lamprey hearts. 100 µg/ml. adrenaline and 400 µg/ml. noradrenaline produced small positive chronotropic and inotropic responses from isolated lamprey hearts. Table 1 shows that these same concentrations of adrenaline and noradrenaline increased the percentage of the phosphorylase enzyme present in the a form.

During the course of these experiments it was observed repeatedly that 4–50 µg/ml. isoprenaline ('Isuprel', Winthrop Laboratories) evoked a marked positive inotropic and chronotropic response from isolated lamprey hearts. In Table 1 it is shown that isoprenaline was more effective than either adrenaline or noradrenaline in converting the enzyme phosphorylase in lamprey hearts from the b to the a form.

In conclusion these results suggest that a parallelism exists between the ability of certain amines to exert a positive inotropic effect on isolated lamprey hearts and their ability to activate the conversion of the enzyme phosphorylase from the b to the a form. It seems unlikely that the endogenous catecholamines present in lamprey hearts participate in the natural regulation of the phosphorylase a/b ratio in this tissue, or that the insensitivity of these hearts to added adrenaline and noradrenaline can be accounted for simply in terms of the percentage of the enzyme which naturally occurs in the a form.

The expenses of this investigation were defrayed by a grant-in-aid from the Life Insurance Medical Research Fund of Australia and New Zealand.

### Isolation of Nucleic Acids from Gelatine

EVIDENCE has accumulated in recent years that the retarding action exerted by some gelatines in the photographic emulsion system is associated with the presence of small amounts of nucleic acids or their breakdown products.

Steigmann first suggested<sup>1,2</sup>, on the basis of the reaction of *p*-dimethylaminobenzaldehyde with gelatine, that pyrimidines and hence nucleic acids were present. However, this reagent is far from specific. The pioneer work in this field is that of Pouradier and Venet<sup>3</sup>, who applied several different tests to gelatine. They concluded from their results that gelatines contain 0.3–2 mg/g of RNA + DNA. Wood<sup>4</sup> and Gordon and Swann<sup>5,6</sup> published papers almost simultaneously on relatively specific methods of determining adenine in gelatine (the latter authors also detected guanine). These contributions have not settled the question in what form the nucleic acid fragments occur in the gelatine. Pouradier and Venet believed, since they observed good agreement between phosphorus and ribose or deoxyribose contents, that nucleic acids were present as such. Gordon and Swann were of the opinion that the phosphate is likely to be removed during gelatine manufacture and hence that the impurities of interest were likely to be present as nucleosides. Wood did not express an opinion. Both these latter authors, however, used hydrolytic procedures and hence detected adenine as such. In the present communication we wish to report work establishing that a high proportion of the adenine is present as high molecular weight, relatively undegraded nucleic acid.

We have been interested in studying the distribution of impurities in gelatine effected by various techniques of fractionation. The method mainly used so far is the alcohol coacervation procedure described by Stainaby<sup>7</sup>. For the nucleic acid work a particular gelatine was chosen. This was 'PG 334' (British Glues and Chemicals), a normal alkali-processed hide gelatine. The initial adenine content, as determined by Gordon and Swann's<sup>8</sup> polarographic technique, was quite high—161 p.p.m. The phosphorus content was determined after nitric-perchloric acid oxidation by King's method<sup>9</sup>; the original gelatine contained 292 p.p.m. These two determinations were done on most of the fractions as an index of the kind of fractionation that had occurred. When the conditions of fractionation were adjusted so that about 15 per cent of the gelatine was precipitated in the first fraction, the adenine content of this fraction (designated N1) was 417 p.p.m. and that of all subsequent fractions (four in all) remained fairly constant at about 20 p.p.m. The phosphorus content increased also in the first fraction but to a slightly less extent. Thus, almost 40 per cent of the adenine-containing impurity appeared in the first fraction. This suggested that the impurity might, like the gelatine itself, have a molecular weight distribution, that a proportion of it was relatively high molecular weight (or insoluble) and that it did not seem to be protein-bound.

Conditions were next adjusted to give a very narrow-cut first fraction—about 3 per cent by weight (designated N6). This was found to contain 3,330 p.p.m. adenine and 5,400 p.p.m. phosphorus. Ribose and deoxyribose were also present. In this case, 62 per cent of the adenine content of the gelatine has been concentrated into this narrow-cut fraction. Further concentration was effected by trypsin digestion of this fraction followed by precipitation with ethanol. In this way we have isolated about 200 mg of a fraction containing 6.3 per cent adenine and 7.5 per cent phosphorus. This fraction (designated N18) contained virtually all the adenine content of the N6 from which it was made, but only 70 per cent of the phosphorus. It is believed to be largely a mixture of DNA and RNA. It gives viscous solutions and is readily precipitated by acid. It is probably in the form of a calcium salt and contains 11.1 per cent moisture. From our

Fig. 1. Ultra-violet absorption spectra in pH 7 buffer. Curve 1, gelatin, 5 g/l; Curve 2, fraction N18, 46.8 mg/l; Curve 3, DNA (herring sperm), 45.8 mg/l.

results, we conclude that the material as isolated contains at least 90 per cent nucleic acids. The gelatine content, via hydroxyproline<sup>10</sup>, was 1.6 per cent. The ribose content was consistent with about 12 per cent RNA, the rest being largely DNA. Ion exchange<sup>10</sup> and paper<sup>11</sup> chromatography established the presence of thymine and cytosine (the first time these pyrimidines have been positively identified in gelatine), but uracil proved more difficult to detect. The identity of the bases was confirmed by their ultra-violet spectra.

Gel filtration on 'Sephadex'<sup>12,13</sup> in phosphate buffer, pH 7, gave a single sharp slightly asymmetrical peak, indicating a molecular weight of the order of 400,000. Ultra-violet spectra of the original gelatine, of fraction N18 and of an authentic sample of DNA are given in Fig. 1. The curves show clearly the similarity of the last two and the enormous difference in optical density between N18 and its source gelatine.

Further work is planned, and this, together with photographic assessment, will be described in fuller detail elsewhere. Thanks are due to the Directors of Minnesota 3M Research, Ltd., for permission to publish this communication.

### Peptide Chains of Tropomyosin

THIS communication reports the determination of the molecular weight of rabbit tropomyosin by equilibrium sedimentation in a solvent consisting of 8 M urea, 0.2 M sodium chloride, 0.025 M sodium dihydrogen phosphate adjusted to pH 7.0, and 0.1 M  $\beta$ -mercaptoethanol. Columns 1 mm high were used and the speed was adjusted so that the weight-average molecular weight could be calculated from the refractive index gradient at the mid-point of the column<sup>1,2</sup>. The results are given in Fig. 1 as a plot of  $1/M_{app}$  versus concentration, expressed as  $\Delta n$ , the refractive index increment. For the molecular weight

Fig. 1. Molecular weight of rabbit tropomyosin as a function of concentration. Rotor speed 14,290 r.p.m., column height 1 mm, temperature of runs 22°. Solvent was 8 M urea, 0.2 M sodium chloride, 0.025 M sodium phosphate, 0.1 M  $\beta$ -mercaptoethanol, pH 7.0. Two preparations (F117 ( $\Delta$ ) and F118 ( $\circ$ )) of tropomyosin were used.

calculations a partial specific volume of 0.728 c.c./g was used, the figure determined by Kay<sup>8</sup> for tropomyosin in 8 M urea. A least-squares line through the points extrapolates to a molecular weight of 34,000.

Rabbit tropomyosin has been shown to be a highly  $\alpha$ -helical protein<sup>4</sup> which exists as a monomer of molecular weight 54,000 (refs. 5 and 6) at pH 2, at pH 7 in high ionic strength buffers, and in 8 M urea. The particle length deduced from hydrodynamic measurements is approximately 400 Å. Since the length of a fully extended  $\alpha$ -chain of this molecular weight would be in the neighbourhood of 680 Å, a double helical structure seems probable. Previous attempts to demonstrate chain separation by performic acid oxidation were not successful<sup>7,8</sup>. Tropomyosin was therefore considered to be cyclic, branched, or to have a hairpin type of structure<sup>9-10</sup>.

The decrease in molecular weight to slightly more than half the monomeric value brought about by  $\beta$ -mercaptoethanol (Fig. 1) suggests that the two chains of tropomyosin are covalently linked by a disulphide bond or bonds, since urea alone does not decrease the molecular weight to this value. The presence of one —S—S— linkage per mole has been reported<sup>11</sup>. A more detailed sedimentation equilibrium study of the molecular weight of tropomyosin and its constituent polypeptide chains is in progress.

### Time Factor in the Action of 5-Fluorodeoxyuridine on the Development of Crown-galls

It has been shown on numerous occasions that the transformation of a normal cell into a crown-gall cell takes place within a period of time which is limited to a few days after infection by *Agrobacterium tumefaciens*<sup>1</sup>. In earlier investigations I showed that the effectiveness of

bromouracil<sup>2</sup> and of 5-fluorodeoxyuridine (FUDR)<sup>3</sup> in inhibiting this transformation is also limited to this period. From these results I concluded that the inhibition applies exclusively to the process of transformation of the host cells and not to the growth of the tumour. In this connexion, strong evidence is provided by experiments in which the inhibition is eliminated by thymidine (TDR). Mennigmann and Szybalski<sup>4,5</sup> have shown that once an inhibition is completed by FUDR it is irreversible if FUDR is allowed to act unhindered for a sufficient length of time and hence for defective molecules of DNA to be formed. A similar mechanism also seems to be present in higher plants<sup>6</sup>. Thus if an inhibition produced by FUDR is no longer capable of being reversed by TDR after five days, it may be due to the fact that either the processes which can be blocked by FUDR have come to an end at this instant, or the inhibition produced by FUDR is no longer reversible. In order to decide which of these alternatives is the correct one it was necessary to choose an experimental approach which could show the selective action of FUDR on the development of a crown gall with the FUDR acting for a constant length of time during the process of transformation.

Leaves of *Kalanchoe daigremontiana* Hamet et Perr (= *Bryophyllum daigremontianum* Berger) were scarified at four places and at the same time inoculated with strain B6 of *Agrobacterium tumefaciens*. FUDR ( $4 \times 0.05$  c.c. of a  $10^{-3}$  M solution per leaf) was then injected into the leaves at 24, 48, 72, 96 and 120 h. At 0, 8, 24 and 32 h after each FUDR injection the same quantities of TDR (concentration  $5 \times 10^{-4}$  mol) were injected. Consequently, starting at different times, the FUDR could always act undisturbed for a constant period of time during the process of transformation. The results are plotted in Fig. 1. The point corresponding to the instant of time at which the FUDR-inhibition was neutralized by TDR has been entered in each case on the curves of the dry weights. In no instance has a treatment of 8 h produced an inhibitory effect, and the same applies when FUDR and TDR are given simultaneously (curve not shown in Fig. 1). In contrast to the simultaneous application the tumours are even promoted after an 8-h treatment. A 24-h treatment exerts a weak inhibitory influence, while one of 32 h, on the other hand, is distinctly inhibitory. Even then it is only the treatment which commences 72 h after infection that gives definite inhibition of crown-galls. Treatments commencing earlier give either weak inhibition or none at all. Similarly, 24- or 32-h treatments do not inhibit if they are applied 96 or 120 h after the infection. In this event, if no TDR after-treatment follows<sup>6</sup>, the inhibition is weak.

The experiment thus showed unequivocally that inhibition can be induced by a 32-h treatment with

Fig. 1. Size of tumour after treatment with FUDR, which begins at different times and lasts for different periods. Ordinate, dry weight of tumour after 4 weeks expressed as a percentage of the control. Abscissa, time after inoculation at which the FUDR treatment was brought to an end by TDR. Each point on the curve represents the mean value from 4 experiments, each with 120 inoculations. —, Curves of the same durations of treatment with FUDR; —, time of inhibition of the transformation by FUDR.

FUDR, which is of limited duration and restricted to the period 72–104 h (4th day) after the infection. According to Braum<sup>7</sup> the crown-galls are completely altered about 4 days after the infection. The strongest action of the FUDR accordingly coincides with this period of time.

The curves in Fig. 1 indicate that the concentration of FUDR used (1) decisively affects only the last part of the process of transformation; (2) does not influence the growth of the tumour after the alteration.

D-Tryptophan is a very strong inhibitor of growth of *Agrobacterium tumefaciens*<sup>8</sup>. If the inhibition of the bacteria by D-tryptophan after infection is measured and plotted on a graph against time, the resulting curve shows no maximum for inhibition after 72 h. From this it can be concluded that FUDR does not take effect by way of the bacteria.

These experiments thus confirm that the process of transformation, limited in time, is inhibited by FUDR. The transformation only occurs when the whole of the DNA capable of functioning is propagated. This propagation of DNA occurs during the transformation<sup>9,10</sup> and probably before the first cell division of the tumour<sup>11</sup>. A proportion of DNA appears to be necessary for the transformation which is in excess of that required for the normal wound divisions and the growth of the tumour, since these proceed undisturbed.

### Excitatory and Depressant Properties of Certain Brain Fractions

ALTHOUGH it is generally believed that at most synapses in the brain 'transmitter' substances are released from nerve endings to excite or inhibit the post-synaptic cells, the identity of the transmitters involved is still very much in doubt. Gray and Whittaker<sup>1</sup> have shown that a fraction of brain homogenates can be prepared containing mainly pinched-off nerve endings. More recently it has been possible to release apparently intact synaptic vesicles from such a nerve-ending fraction and to separate them from other membrane structures by density-gradient centrifugation<sup>2</sup>. The purified vesicle fraction contains acetylcholine but not the other components of the acetylcholine system. Since nerve endings can be expected to contain substantial amounts of various transmitter substances, we have examined the excitatory and depressant effects produced by various subfractions of guinea-pig brain, when applied from micropipettes to single units in the guinea-pig's cerebral cortex.

The fractions mainly used were the O and D fractions prepared from hypotonically disrupted cortical nerve endings by density-gradient separation as previously described<sup>3</sup>. Fraction O contained the soluble cytoplasmic constituents of the nerve endings. Fraction D consisted of a

suspension of synaptic vesicles. This fraction was treated in various ways to release the soluble constituents of the vesicles. All the material obtained was made up in sucrose solutions (approximately 0.5 M) and immediately inserted by centrifuging into multi-barrelled glass micropipettes of the type used in previous studies of mammalian cortical neurones<sup>4</sup>. When small electrical currents are passed through such solutions, which have a low conductivity, electro-osmotic movements of fluid can be expected to release a substantial amount of the solution from the tip of the pipette<sup>5</sup>. Using sucrose solutions labelled with <sup>14</sup>C or containing polystyrene beads, we have confirmed that such an electro-osmotic outflow does occur; under the conditions of our experiments, this reached a maximum of about 10<sup>-6</sup> ml./μcoulomb. Fractions O and D and various subfractions of D had a positive zeta potential with respect to the glass of the micropipettes, and they could therefore be expelled from the tip by making the lumen relatively positive. This method of application is much less reliable than iontophoresis, because the outflow is very susceptible to obstructions of the lumen.

All the D fractions and subfractions had a clearly depressant action on cortical neurones whereas simple solutions of sucrose or O fractions produced only minimal effects (Fig. 1). Spontaneous discharges, or firing evoked by the simultaneous application of L-glutamate or acetylcholine, were rapidly blocked by passing 60–80 nA through barrels containing D. This suggests that synaptic vesicles are associated with some substance capable of depressing neuronal activity. Excitatory effects were not seen even when the preparations were applied to cholinceptive cells; thus any effect of the acetylcholine present in the preparations was masked by the depressant effects.

Hypotonic or supersonic treatment of D gave subfractions of substantially greater potency, particularly in the supernatants obtained after sedimenting particulate material in the ultracentrifuge, presumably because of the release of soluble active factors from the vesicles. With the most active preparation enough was released by a current of 10 nA to cause a prolonged block of discharge. In this respect the suspension was comparable in depressant potency to neutral solutions of γ-aminobutyric acid<sup>6</sup>.

Amino-acid analyses of these fractions<sup>7</sup> revealed a substantial content of some amino-acids, including L-glutamate and aspartate, both of which strongly excite cortical neurones<sup>8</sup>, and γ-aminobutyric acid; it was shown, moreover, that similar mixtures of amino-acids prepared artificially also had mainly depressant effects on cortical neurones when applied in this way, presumably because the outward currents used would tend to prevent the release of the negatively charged excitatory amino-acids. Clear excitatory effects, which could be attributed to the release of these acids, have only been seen with extracts of

Fig. 1. Excitation of cerebral cortical unit of guinea-pig by (A) L-glutamate and (B) acetylcholine. In A, superimposed electro-osmotic applications of a suspension of synaptic vesicles in sucrose at 80 nA (D80, white bar) blocked the glutamate-induced discharge, whereas a fraction containing the soluble cytoplasmic components of the nerve endings applied in the same way (O80, between small arrows) had little or no effect. Similar results were obtained during firing induced by acetylcholine (lower trace). Dial anaesthesia.

a nerve-ending fraction (B), suspensions of which in sucrose had a negative zeta potential with respect to the glass of the micropipettes.

Although there is thus some reason for believing that enough  $\gamma$ -aminobutyric acid is present in D and its sub-fractions to cause a marked depression of cortical neurones, the subfractions of D in several instances had a strong and prolonged depressant effect on the amplitude of the neuronal spikes, which sometimes did not return to normal for several minutes after a short application. This kind of effect is never seen with  $\gamma$ -aminobutyric acid alone, and its occurrence suggests that some other potent factor or factors, with a different kind of action, may also be present in these fractions. Whether these play a part in normal function or whether they are artefacts arising from an unphysiological degradation of larger molecules cannot be decided at present.

## PHYSIOLOGY

### Effect of Electrical Stimulation on Uptake and Release of Calcium by the Endoplasmic Reticulum

OVER the past decade the concept has been developed that  $\text{Ca}^{++}$  is a mediator of the so-called excitation-contraction coupling in muscle contraction and that the 'calcium pump' of the endoplasmic reticulum is responsible for relaxation<sup>1-3</sup>. According to this concept the electrical excitation of muscle membranes releases  $\text{Ca}^{++}$  from the endoplasmic reticulum and the released  $\text{Ca}^{++}$  in turn triggers myofibrils to contract. Relaxation then occurs when the released  $\text{Ca}^{++}$  is again taken up by the endoplasmic reticulum. However, as yet, no experimental evidence is available which directly supports the concept that following membrane excitation there is a release of  $\text{Ca}^{++}$ . In this communication, experimental results are presented which provide direct evidence in support of the concept that electrical stimulation releases stored  $\text{Ca}^{++}$  from the endoplasmic reticulum and that the cessation of electrical stimulation is followed by re-uptake of  $\text{Ca}^{++}$  by this system.

The investigation was concerned with the effect of electrical impulses passing through a suspension of microsomal relaxing factor on the uptake and release of  $\text{Ca}^{++}$  by the relaxing factor. The relaxing factor, which has been shown to consist principally of fragments of the endoplasmic reticulum, was prepared from rabbit skeletal muscle with some modification, according to the method of Weber *et al.*<sup>4</sup>. The uptake of  $\text{Ca}^{++}$  by the relaxing factor from the suspending medium was determined by the measurement of radioactivity of the medium filtered through a 'Millipore' filter, as described by Martonosi and Ferencsik<sup>5</sup>, following the incubation of the relaxing factor in the medium. The basic medium contained 3 mM  $\text{MgCl}_2$ , 1 mM ATP, 5 mM creatine phosphate (CP), 0.1 mg/ml. creatine phosphokinase, 50  $\mu\text{M}$  of total  $\text{CaCl}_2$  +  $\text{Ca}^{++}\text{Cl}_2$ , 0.08 M KCl and 0.01 M tris-maleate buffer, pH 6.5. Sets of

'Millipore' filters (25 mm diameter, type HS or GS, with 0.45 to 0.8  $\mu$  average pore diameter) were mounted on test tubes with side arms connected to a vacuum line which was closed during incubation of the mixture. One to one-half ml. of reaction mixture containing the relaxing factor (0.5-0.8 mg protein/ml.) was incubated in the tube above the filter disk. During the incubation period, a pair of flat platinum electrodes was immersed in the medium, and when electrical stimulation was desired, square wave pulses of 2 V and 10 msec duration were passed through the medium at a frequency of 80 impulses/min. The electrodes were 5 mm wide, and were separated by a gap of 4 mm. After the desired period of incubation, the medium was filtered through the 'Millipore' filter by opening the vacuum line connected to the side arm, and the radioactivity of the filtrate was measured. The amount of  $\text{Ca}^{++}$  bound to the microsomal relaxing factor was calculated from the difference between the radioactivity of the filtrates of relaxing factor-free incubation medium and of the relaxing factor-containing samples. The protein content was determined by the biuret method.

Table 1

Condition of incubation	Relative radioactivity of filtrate	$\mu\text{Moles Ca}^{++}$ taken up per mg protein relaxing factor
3 min in basic medium without ATP and CP	1.00	0.01
3 min without electrical stimulation	$0.13 \pm 0.08$	0.088
3 min with electrical stimulation	$0.66 \pm 0.1$	0.034
First 3 min without electrical stimulation	$0.71 \pm 0.09$	0.026
Second 3 min with electrical stimulation		
First 3 min with electrical stimulation	$0.21 \pm 0.07$	0.06
Second 3 min without electrical stimulation		

All incubations except the first were carried out at 25° in the basic medium (see text). Values in second column are mean values  $\pm$  S.E. calculated for six experiments.

The results are shown in Table 1 and Fig. 1. As can be seen in Table 1, the relaxing factor prepared by this method was found to take up  $\text{Ca}^{++}$  actively from the basic medium. Without ATP and CP, there was no significant  $\text{Ca}^{++}$  uptake. During the 3- or 6-min incubation periods in the presence of ATP and CP without electrical impulses passing through the electrodes (without stimulation), an average of 88 per cent of  $\text{Ca}^{++}$  present in the medium was taken up by the relaxing factor, leaving only 12 per cent in the filtrate. When electrical stimulation was passed through the mixture during the incubation period, only about 34 per cent of the  $\text{Ca}^{++}$  was taken up by the relaxing factor, leaving 66 per cent in the medium. This indicates that electrical stimulation inhibits  $\text{Ca}^{++}$  uptake by the relaxing factor. When a 3-min incubation period without electrical stimulation was followed by a 3-min incubation period with electrical stimulation, only 29 per cent of the

$\text{Ca}^{++}$  in the medium was taken up by the relaxing factor. This indicates that most of the  $\text{Ca}^{++}$  which was taken up by the relaxing factor during the first 3 min of the incubation period without electrical stimulation is released during the latter period with electrical stimulation. On the other hand, when a 3-min incubation with electrical stimulation was followed by a 3-min incubation without electrical stimulation, 79 per cent of the  $\text{Ca}^{++}$  was taken up by the relaxing factor. This indicates that the  $\text{Ca}^{++}$  which was not taken up during the first 3-min incubation period with electrical stimulation was afterwards taken up during the later incubation period without electrical stimulation.

The foregoing interpretation that  $\text{Ca}^{++}$  is taken up by the relaxing factor during the absence of electrical stimulation and is released from the relaxing factor during the stimulation is further supported by the results shown in Fig. 1. In this experiment, 2 mg protein of the relaxing factor was incubated in 4 ml. of the basic medium and every 3 min a 0.2-ml. sample was immediately filtered through a 'Millipore' filter and the radioactivity of the filtrate was measured. As can be seen in Fig. 1, following the addition of ATP and CP, the  $\text{Ca}^{++}$  content of the filtrate fell precipitously. When the medium was stimulated electrically, the  $\text{Ca}^{++}$  content of the filtrate increased, indicating that  $\text{Ca}^{++}$  taken up previously by the relaxing factor was released during electrical stimulation. The cessation of electrical stimulation was followed by re-uptake of  $\text{Ca}^{++}$  by the relaxing factor from the medium.

The results obtained are considered to demonstrate directly in an *in vitro* system that the passage of electrical impulses through the microsomal suspension releases  $\text{Ca}^{++}$  from the relaxing factor and the cessation of electrical stimulation is followed by uptake of  $\text{Ca}^{++}$  by the relaxing factor. Since the microsomal relaxing factor consists primarily of fragments of the endoplasmic reticulum of muscle, presumably the electrical stimulation of the endoplasmic reticulum occurring during the passage of an action potential would release  $\text{Ca}^{++}$  from this system *in situ* and the released  $\text{Ca}^{++}$  would initiate contraction of the myofibrils. After the termination of the electrical stimulation,  $\text{Ca}^{++}$  would again be taken up by the endoplasmic reticulum and relaxation would then ensue. The present experiments may be considered an *in vitro* demonstration of the  $\text{Ca}^{++}$  release from the endoplasmic reticulum which occurs *in vivo* during excitation-contraction coupling and the  $\text{Ca}^{++}$  uptake by this system which occurs during relaxation.

### Electrophoretic Mobilities of Tissue Culture Cells in Exponential and Parasynchronous Growth

It has been reported<sup>1,2</sup> that tumour cells have a higher net negative charge than their normal counterparts and that the net negative charge of tumour cells increases with increased invasiveness. It was further reported that decreased mutual adhesiveness of cells is correlated with increased surface charge<sup>3</sup>. From observations of electrophoretic mobilities of rat liver cells<sup>4</sup> and mouse fibroblasts<sup>5</sup> it was suggested that increased negative charge is asso-

ciated with increased growth rate, and Eisenberg *et al.*<sup>6</sup> showed that cell populations with increased growth rate have increased heterogeneity in electrophoretic mobilities. Cook *et al.*<sup>7</sup> inferred from the small scatter of electrophoretic mobilities of individual Ehrlich ascites tumour cells that 'the electrokinetic properties of the tumour cell surface were independent of the state of the nucleus'. This communication describes an attempt to relate the electrophoretic mobility of cells to their stage in the mitotic cycle.

The electrophoretic mobilities of cells from cultures partially synchronized by double thymidine blocking<sup>8,9</sup> were compared with those of cells from unsynchronized cultures. Roswell Park Memorial Institute (R.P.M.I.) No. 41 cells, derived from a human osteogenic sarcoma<sup>10</sup>, cultured at 37° C in suspension in medium R.P.M.I. 906 plus 5 per cent calf serum<sup>11</sup>, and having a mean generation time of 18–20 h<sup>12</sup>, were used throughout. Thymidine was added to cultures which had been growing exponentially for at least 5 generations, to give a final concentration of 5–10 mM. After 14–24 h incubation the cells were washed twice and resuspended in fresh medium and 8–14 h later the treatment with thymidine was repeated. After a further 14–24 h, the cells were washed twice, resuspended in fresh warm medium, and sampled at hourly or half-hourly intervals for determination of cell concentration and mitotic index. The mitotic peak occurred 14–17 h after stopping the thymidine treatment, when a maximum of 15 per cent of the cells were in mitosis, compared with 2–3 per cent in unsynchronized cultures. The degree of synchronization<sup>13</sup> varied in different experiments between 65 and 80 per cent for the first generation, after which the degree of synchronization decayed with time as described by Petersen and Anderson<sup>8</sup>. No differences were detected between the number of viable cells as determined by uptake of trypan blue in partially synchronized (parasynchronous) cultures and control cultures in exponential growth. Parasynchronous cultures grew at the same rate as control cultures for at least 8 generations after release from thymidine. Thus thymidine at the doses used did not damage the cells.

Cell suspensions, removed either from control cultures or from cultures at various times after release from thymidine, were prepared for electrophoresis measurements in one of the following ways: (a) The cells were washed twice by centrifugation in Ca saline (0.145 M sodium chloride;  $5 \times 10^{-3}$  M calcium chloride;  $4 \times 10^{-4}$  M sodium bicarbonate) and resuspended in 4 per cent phosphate buffered formaldehyde solution (pH 7.2). After fixation for 20–24 h, the cells were washed twice in isotonic 5 per cent sucrose in half-strength Hanks's balanced salt solution at pH 7.7  $\pm$  0.2, and resuspended for electrophoresis in this solution. (b) 10 ml. buffered formaldehyde was added to 100 ml. cell suspension and left for 20–24 h. The cells were then washed and resuspended for electrophoresis in sucrose/Hanks's solution as in (a). (c) 100 ml. fresh cell suspension was washed twice and resuspended for electrophoresis in sucrose/Hanks's solution.

The times taken for individual cells to traverse 25  $\mu$  at 25° C, 50 V and 0.9 mamp, in a cylindrical chamber electrophoresis apparatus<sup>14</sup>, were measured, and the electrophoretic mobilities calculated. The results are shown in Table 1.

The significance of the difference in means between cells from control cultures and cells in various phases from parasynchronous cultures was determined by means of *t*-tests. Mitotic peak phase cells, comprising dividing cells, cells just before division ( $G_2$ ) and just after division ( $G_1$ ), have significantly higher mean mobilities than corresponding control cells. Cells during DNA synthesis (after release from thymidine) have mobilities similar to, or lower than, control cells and after division the mobility falls to the control value; thus increased mobility of cells during the mitotic peak phase is due to synchronization and not to thymidine treatment.

Table 1. ELECTROPHORETIC MOBILITIES OF FIXED AND FRESH R.P.M.L. No. 41 CELLS FROM CONTROL OR PARASYNCHRONOUS CULTURES

Treatment of cells after removal from culture	Type of culture growth	Phase of mitotic cycle	Number of cells measured	Mobility ( $\mu\text{sec}^{-1}\text{V}^{-1}\text{cm}$ ) $\pm$ S.E.	t-test, p-value. Controls v. parasyynchronous phase
Fixed method (a)	control (exponential)	—	118	$-1.46 \pm 0.027$	—
	parasyynchronous	mitotic peak	40	$-1.82 \pm 0.063$	<0.001
Fixed method (b)	control (exponential)	—	157	$-1.13 \pm 0.030$	—
	parasyynchronous	DNA synthesis	180	$-1.07 \pm 0.034$	<0.1, >0.05
	parasyynchronous	late DNA synthesis	181	$-1.13 \pm 0.033$	>0.9
	parasyynchronous	mitotic peak	117	$-1.37 \pm 0.037$	<0.001
	parasyynchronous	post division ( $G_1$ )	106	$-1.16 \pm 0.034$	>0.40
Fresh (c)	control (exponential)	—	150	$-1.06 \pm 0.023$	—
	parasyynchronous	mitotic peak	257	$-1.26 \pm 0.021$	<0.001
Fresh (d)	control (exponential)	—	200	$-1.05 \pm 0.020$	—
	parasyynchronous	DNA synthesis	145	$-1.00 \pm 0.022$	<0.1, >0.06
	parasyynchronous	mitotic peak	189	$-1.29 \pm 0.023$	<0.001
	parasyynchronous	post division ( $G_1$ phase)	168	$-1.12 \pm 0.032$	<0.1, >0.06

Control cells fixed in formalin by method (a) have a higher mobility than those fixed by method (b). Method (a) fixation is similar to that used by Cook *et al.*<sup>7</sup>, who also found increased mobility of fixed compared with fresh cells. It seems that the fixation procedure can affect the mobilities of the cells, but that comparatively gentle fixation, as in method (b), gives results similar to those obtained for fresh cells.

We thank Dr. Stig Nordling and Dr. L. Weiss for helpful discussions. Some of the costs of the work were covered by a grant, G-64-RP-5, from the United Health Foundation of Western New York.

Fig. 1. Histograms of electrophoretic mobilities of fresh R.P.M.L. No. 41 cells from control and parasyynchronous cultures measured in sucrose/Hanks's solution at 25° C

Fig. 1 shows histograms of electrophoretic mobilities of fresh cells from control and parasyynchronous cultures. Cells from mitotic peak phase have a wider scatter in mobilities compared with those from the DNA synthesis phase, after division or controls, and there are a number of cells with mobilities 2 or more times greater than the mean.

If these results, which have been obtained on only one type of cultured cell, have a general validity, it may well be that the electrophoretic mobility of cells varies during the mitotic cycle, and indicates an increase in negative charge density (possibly due to an increase in negatively charged groups and/or a decrease in positively charged groups at the cell periphery). Changes in surface charge could possibly affect the adsorption of drugs etc.; this would possibly account for variation in sensitivity to cytotoxic drugs at different stages of the mitotic cycle<sup>18,19</sup>.

## Effects of Tenotomy on the Growth of Muscle and its Tendon

THE immediate changes which occur in an adult muscle after section of its tendon have been summarized by Sunderland and Lavarack<sup>1</sup>. Regeneration of an experimentally transected tendon occurs within 2-3 weeks<sup>2,3</sup> even where the muscle has been denervated previously<sup>4</sup>, and some muscle function is thus soon restored. Because the dysfunction appears to be only temporary, the possibility of some permanent effect on the muscle has been overlooked even though it has been shown<sup>5,6</sup> that, six weeks after tenotomy, the repaired tendon is longer while its muscle remains both shorter and lighter than the control. Therefore, in an investigation of the relationship between the strength of a muscle and the collagen content of its tendon<sup>7</sup>, the operation of tenotomy was included to modify the normal muscle-tendon relationship during growth. The tendon of tibialis anterior was transected just distal to the muscle-tendon junction in the right hind-limb of five 4-week-old rabbits, the other limb serving as a control. The stumps were not sutured but allowed to retract. The animals made an uneventful recovery and were killed when 180 days old. No adhesions were present at the site of tendon repair.

Contrary to expectations the experimental muscle belly was not shorter but either the same length or even longer than the control and it was also significantly heavier ( $P=0.05$ , Table 1), thus having an increased girth in four of the five rabbits. There is no obvious explanation for this hypertrophy; but it has already been shown<sup>8</sup> that the diminution of electro-myographic activity four months after tenotomy is not due to atrophy since it is

Table 1

Rabbit No.:	1	2	3	4	5
Wet weight of control muscle belly (g)	2.80	2.80	2.19	2.30	2.52
Wet weight of experimental muscle belly (g)	2.51	2.80	2.78	2.46	2.49
Length of control muscle belly (mm)	72	79	72	75	76
Length of experimental muscle belly (mm)	73	86	79	75	76
Experimental muscle girth (weight/length) as % of control	108	109	117	107	99
Thickness of control tendon (mg dry weight/mm)	0.37	0.36	0.36	0.40	0.40
Experimental tendon thickness as % of control	117	123	114	114	97

normal or even increased during postural reflexes in the anaesthetized rabbit.

There was no significant difference between the mean increase of the girth of the muscle and that of its tendon when each was expressed as a percentage of the control. There were  $69.0 \pm 1.0$  mg collagen per 100 mg dry weight of the normal tendon and  $67.4 \pm 1.8$  of the experimental, distal to the tenotomy, estimated according to the method of Neuman and Logan<sup>8</sup>. At the actual site of regeneration the tendon was too small for its girth or collagen content to be assessed. The correlation between the increased girth of the tendon distal to the site of tenotomy and the increased girth of its muscle belly is in accordance with the similar relationship found when the muscle is stimulated to hypertrophy during growth by removal of synergic muscles<sup>10</sup>, by exercise<sup>11</sup>, or by immobilization at an extended length<sup>7,10</sup>.

### Anoxia-Induced Release of Noradrenaline from the Isolated Perfused Heart

DECREASES in the catecholamine content of the myocardium have been found to occur in animals subjected to prolonged periods of hypoxia<sup>1</sup> and of myocardial ischaemia<sup>2</sup>. Results recently obtained in this laboratory<sup>3,4</sup>, however, suggest that release and subsequent loss of cardiac catecholamines from their storage site may be a more immediate response of the animal to arrest of the coronary circulation and to myocardial anoxia in general. In the work recorded here the isolated perfused heart was selected as a suitable object for approaching this problem experimentally and, at the same time, independently of the influence of nervous activity. Using the isolated perfused adrenal gland Bülbring *et al.*<sup>5</sup> and Cession-Fossion<sup>6</sup> had been able to demonstrate a direct mobilizing action of anoxia on the adrenaline stores of this organ.

The hearts of heparinized and anaesthetized adult rabbits and rats were rapidly excised and attached to a Langendorff apparatus for perfusion through the aorta and the coronary circulation with glucose and sucrose-containing Tyrode solution aerated with a mixture of 95 per cent oxygen and 5 per cent carbon dioxide. The time elapsing between opening of the thorax and the start of perfusion did not exceed 1 min. After 30–35 min of perfusion at 34° C the hearts were left for 3 or 4 min in an anaerobic state, brought about in one series of experiments by arresting the perfusion, and in the other series by connecting the aortic cannula by means of a three-way

stopcock to a second infusion system in which the Tyrode solution was equilibrated with a mixture of 95 per cent nitrogen and 5 per cent carbon dioxide. Aerobic perfusion was then re-started. The perfusate was collected in consecutive fractions of 10–100 ml. in graduated shaking cylinders containing 0.1 volume of 1 N perchloric acid. Noradrenaline in the perfusate fractions, in the ventricular muscle, and in various sub-cellular fractions of this tissue was determined, after adsorption on aluminium oxide at pH 8.3 and elution with 0.1 N perchloric acid, by a modification<sup>7</sup> of the trihydroxyindole fluorometric method.

Both the interruption of perfusion and the shift to anaerobic Tyrode solution caused the discharge of considerable amounts of noradrenaline from the heart into the circulation. A representative experiment on a rabbit heart, illustrating the magnitude and time course of this response, is depicted in Fig. 1. During the steady aerobic state negligible amounts of the catecholamine appeared in the coronary outflow. A 3-min period of anaerobiosis, in this instance due to arrest of perfusion, led to the subsequent release into the circulation of a total of 5 µg of noradrenaline or, reckoned per g heart, of 0.7 µg/g. The mean loss of noradrenaline caused by 3 or 4 min of anaerobiosis from 11 preparations of rabbit hearts was 0.46 µg/g. This amount represents nearly one-fourth of the noradrenaline normally present in the rabbit's heart. The highest concentration of the catecholamine in the perfusate was found in the fractions collected during the second or third minute following return to aerobic conditions (Fig. 1). Thereafter the noradrenaline output fell rapidly toward or even below the pre-anaerobic level. A renewed output of the neurotransmitter was elicited in some preparations by a second exposure to anoxic conditions. At the end of these experiments the hearts were found to contain considerably less noradrenaline than hearts perfused for the same length of time without an intervening period of anoxia. No appreciable difference, however, was seen in the sub-cellular distribution of the amine as revealed by analyses of heart homogenate fractions separated by differential centrifugation.

Concomitantly with the anoxia-induced discharge of noradrenaline into the circulation there was a sharp rise in the lactic acid concentration in the perfusate. At its peak the lactic acid output by the heart approached 1–4 µmoles/g heart/min. It is conceivable that accumulation of lactic acid and other acid metabolites in the anoxic and post-anoxic myocardium may have significantly contributed, perhaps through an increase in the hydrogen ion concentration, to the liberation of noradrenaline<sup>8</sup>. This point is currently being investigated.

Fig. 1 Output of noradrenaline from the perfused rabbit heart before and after a 3-min arrest of perfusion. The period of arrest of perfusion is denoted by the row of oblique bars. Rabbit No. 15. Weight of heart at the end of the experiment, 7.1 g

When the isolated hearts of rabbits which had just been treated for 10 days with reserpine (0.1 mg/kg daily) were subjected to anoxia for 4 min, much less noradrenaline was released into the coronary bed than from the hearts of the untreated animals. The amounts released were proportional to the size of the rather severely depleted cardiac noradrenaline stores. No release of noradrenaline whatever was observed in preparations of rabbit hearts which had undergone only moderately severe losses of noradrenaline as a result of prior administration of tyramine (30 mg/kg rabbit given 30 min before excision of the heart). This finding suggests that the anoxia-sensitive fraction of the noradrenaline in the rabbit heart might form part of, or be identical with, the fraction releasable by tyramine.

Further characterization of the material in the perfusates at present determined as noradrenaline is provided by the following observations: (1) The fluorescence excitation and emission spectra of the alumina eluates of the perfusates treated by the trihydroxyindole procedure used<sup>7</sup> were indistinguishable from those of the lutine formed from authentic noradrenaline. (2) The blood-pressure-raising activity of the alumina eluates, assayed in the cat, corresponded roughly to that of the fluorometrically estimated quantities of noradrenaline in these eluates. (3) In heart preparations loaded with tritium-labelled noradrenaline a 4-min arrest of perfusion was followed by a sharp temporary rise in the rate of outflow of radioactive noradrenaline.

There is thus little doubt that myocardial anoxia can bring about, in the apparent absence of sympathetic nerve activity and with little delay, the release and loss of a good part of the noradrenaline stored in cardiac muscle. The liberation of the adrenergic transmitter may be held largely responsible for the initial outburst of phosphorylase activity and glycolysis in anoxic myocardium<sup>3,4</sup> and may conceivably play a part in the genesis of cardiac arrhythmias such as occur in the wake of an occlusion of a coronary vessel<sup>5</sup>.

## PHARMACOLOGY

### Reserpine in a Tissue Culture of *Alstonia constricta* F. Muell

In a tissue culture study of certain members of the Apocynaceae, the plant *Alstonia constricta* F. Muell was investigated. The root and trunk barks of this tree, which is native to Australia, have been known to yield several indole alkaloids including reserpine<sup>1-4</sup>.

The callus tissue cultures were initiated from germinating seeds and maintained on a modified White's medium which included 2,4-dichlorophenoxyacetic acid, 1 mg/l., and 10 per cent coconut water<sup>5</sup>. The tissue was continuously cultivated for over two years and periodically it was gathered, lyophilized and stored for subsequent chemical analysis.

Recently, a preliminary chemical analysis was performed. Several grams of dried callus were reduced to a

number 20 powder and the powdered tissue was extracted for alkaloids according to a slight modification of the procedure reported by Svoboda<sup>1</sup>. This procedure involves the use of several solvents, the final one being chloroform. The chloroform extract was subjected to analysis by thin-layer chromatography. In this procedure the Deaga<sup>1</sup> apparatus (Brinkman Instrument Co., Westbury, New York) was used, including 200 mm square plates with a matrix of 'Silica Gel G' of Merck and a solvent system of ethyl acetate: ethanol 3:1. The solvent front was allowed to travel 100 mm. Each chromatogram was examined under ultra-violet light and its fluorescent pattern was recorded. The plates were then sprayed with modified Dragendorff's reagent<sup>6</sup>. Since reserpine had previously been reported to occur in root and stem bark of *Alstonia*, this compound was chromatographed alongside the callus extracts.

An examination of the chromatograms under ultra-violet light revealed the presence of five fluorescent spots. Four of these gave a blue fluorescence and one a yellow-green colour. The pure reserpine also fluoresced yellow-green and appeared at the same  $R_f$  as the yellow-green fluorescent spot from the callus extract. When the plates had been sprayed with modified Dragendorff's reagent three distinct positive spots appeared with  $R_f$  values of 0.19, 0.68 and 0.93. The  $R_f$  of reserpine under the same conditions corresponded to the middle value just listed, 0.68.

Further, to check the possibility that one of the unknown alkaloids was reserpine, the compound appearing at  $R_f$  0.68 as well as known reserpine was scraped from the plate before spraying with modified Dragendorff's reagent. The alkaloid-silica-gel matrix was eluted with chloroform by mixing in a centrifuge tube. The mixture was centrifuged and the supernatant chloroform extract removed. This extract was analysed spectrophotometrically in a Beckman DK-2 recording spectrophotometer.

The ultra-violet spectrum for the alkaloid at  $R_f$  0.68 was the same as for reserpine, namely a shoulder at 290 $\mu$  and a maximum at 267 $\mu$ . More tissue is being accumulated so that further investigation may be performed. From this preliminary work it appears that our tissue culture of *A. constricta*, which has been maintained for more than two years, has the capacity to biosynthesize reserpine.

### Effect of Cold and Restriction of Movement on Mast Cells and Metachromasia of Rat Skin

SYSTEMIC administration of corticotrophin, cortisone and hydrocortisone causes degranulation and other changes in mast cells<sup>1-3</sup>. Exposure of rats to cold caused the number of mast cells in lung and thymus tissue to increase in rats weighing 185 g and decrease in rats weighing 380 g (ref. 4). Cold treatment of the heavier rats increased the number of dermal mast cells and decreased mesenteric (intervascular) mast cells<sup>5</sup>.

Fediay and Clay<sup>6</sup> reported that treatment of rats weighing 300 g for 2 days with cold and restriction of movement increased plasma corticosterone levels, decreased dermal

hyaluronic acid and chondroitin sulphate levels and decreased dermal spread of hyaluronidase-indian ink solution. After 14 days treatment corticosterone-levels remained elevated, hyaluronic acid and chondroitin sulphate increased, heparin decreased, and the spread of the hyaluronidase-indian ink solution increased. In the work recorded here samples of skin were taken from the rats to determine whether changes in the physical and chemical state of the skin can be correlated with changes in dermal metachromasia and mast cells.

Three groups of eight male Wistar rats (280–340 g) were treated as follows: group 1, control; groups 2 and 3, maintained in individual steel cages at  $12^{\circ} \pm 2^{\circ} \text{C}$  for 2 and 14 days, respectively. The dimensions of the cages (5.5 in.  $\times$  2.5 in.  $\times$  2.5 in.) permitted the rats to move only with difficulty. The rats were decapitated and full-thickness skin samples were cut from the shaved right flanks and fixed in 10 per cent neutral formalin. Frozen cross-sections (30–33 $\mu$ ) were cut and stained for 40 sec in a 0.5 per cent toluidine blue water solution. Intensity of ground substance metachromasia was recorded. Mast cells were counted by a modification of the method of Simpson and Hyashi<sup>7</sup> in 10 sections from each skin sample. Counts were made in square fields (0.25 mm  $\times$  0.25 mm) extending through the entire skin. Five such columns of fields were selected for each tissue section. Separate cell counts were made according to regional distribution or zone and cellular morphological characteristics. The zones are as follows: 1, immediately below the basal layer of the epidermis; 2, dermis; 3, subcutaneous tissue; 4, panniculus carnosus. The cell types are as follows: 1, heavily granulated, larger than 0.007 mm; 2, lightly granulated, larger than 0.007 mm; 3, heavily granulated, smaller than 0.007 mm; 4, lightly granulated, smaller than 0.007 mm; 5, mast cells with ruptured walls.

Table 1 shows an increase in the mean mast cell density (5 cell types, 4 zones) after 14 days of stress, which was due primarily to an increase in cell type 5, cells with ruptured cell walls (control, 4.812; 2-day stress, 4.561; 14-day stress, 12.465). The skin, after 14 days of stress, showed many areas containing individually dispersed extracellular metachromatic granules, cells with granules clumped together in irregular and angular shapes as well as areas of the ground substance which failed to stain metachromatically. The highest mast cell density in each of the 3 groups was found in zone 3, followed by zones 4, 2

## HAEMATOLOGY

### Separation of Factor VIII (Antihæmophilic Factor) Activity from Fibrinogen by Means of a Snake Venom

THE separation of Factor VIII activity from fibrinogen is of considerable importance. From the therapeutic point of view it would seem desirable when treating hæmophilias to use a protein fraction rich in factor VIII activity but as free as possible from other contaminating proteins, including fibrinogen. From the experimental point of view purified Factor VIII is required for studies of its chemical and physical properties.

Many attempts have been made to prepare plasma fractions rich in Factor VIII but free of fibrinogen<sup>1-7</sup>. Most of the procedures used have been only partially successful or have yielded inconsistent results.

In 1963 Reid, Chan and Thean<sup>8</sup> observed that human beings bitten by the Malayan pit viper (*Ancistrodon rhodostoma*) developed a prolonged defibrination state which was not associated with a severe bleeding tendency. Thromboplastin generation tests carried out on the blood of these fibrinogenopenic subjects was normal, suggesting that there was no loss of activity of the factors necessary for thromboplastin formation. We were particularly interested in the possibility that the venom did not reduce Factor VIII activity and might therefore be used *in vitro* to prepare plasma deficient in fibrinogen but containing Factor VIII.

Experiments were carried out in which citrated normal human plasma was incubated at 37° C with different concentrations of the crude venom for different periods of time and the residual Factor VIII activity in the plasma assayed (Table 1). The assay method used was that of Biggs, Eveling and Richards as modified by Biggs and Macfarlane<sup>9</sup>. After incubation for 1 h with final venom concentrations of 1–2  $\mu\text{g/ml}$ , the plasma fibrinogen clotted but without any loss of Factor VIII activity. On the contrary there was an apparent increase of activity in these samples. With a venom concentration of 4  $\mu\text{g/ml}$  there was slight loss of Factor VIII activity at 1 hr and with higher concentrations of venom and prolonged incubation the loss of activity became more marked. With venom concentrations above 1  $\mu\text{g/ml}$ , defibrination of the plasma seemed to be complete, since subsequent addition of a strong solution of thrombin ('Thrombin Topical', Parke Davis) produced no further clotting in the plasma. As a further check on the completeness of fibrinogen conversion by the venom, samples of plasma were clotted by the addition of either viper venom (1–4  $\mu\text{g/ml}$ ) or M/40

Table 1

Final venom concentration in plasma (μg/ml)	Residual Factor VIII activity after incubation for:		
	1 h	2 h	4 h
0.5	150	120	—
1	135	100	75
2	115	78	70
4	62	56	33
5	58	—	—
10	<10	—	—
Buffer	100	100	100

Incubation system: 3.6 ml. plasma + 0.4 ml. glycylalane buffer or solution of venom in buffer. After 1, 2 and 4 h incubation at 37° C, 1 ml. incubation mixture was removed from each tube, adsorbed with Al(OH)<sub>3</sub>, and assayed for Factor VIII activity. The residual Factor VIII activity was expressed as a percentage of the buffered plasma sample incubated for the same length of time.

CaCl<sub>2</sub>. After incubation at 37° C for 1 h the fibrin clots formed were washed in saline, digested and assayed for total nitrogen content by the micro-Kjeldahl method. It was found that the amount of fibrin formed by the action of the venom was the same as the amount formed when the plasma was clotted by recalcification.

With alumina-adsorbed fibrinogen-free plasma as starting material, attempts were made to precipitate Factor VIII activity by the alcohol fractionation procedure of Cohn<sup>10</sup>. Whereas in normal plasma Factor VIII is precipitated along with fibrinogen in Fraction I at a final ethanol concentration of 8 per cent, we found that in the defibrinated plasma maximal precipitation of Factor VIII activity took place at a final ethanol concentration of 15 per cent. It is well recognized that the precipitation characteristics of plasma proteins are altered in the absence of fibrinogen, and Gobbi<sup>11</sup> has shown that higher concentrations of alcohol are required to precipitate Factor VIII activity from the plasma of patients with congenital afibrinogenemia than from normal plasma.

The action of the venom in clotting plasma fibrinogen and yet sparing Factor VIII is consistent and reproducible and it should be possible by its means to prepare fibrinogen-free Factor VIII for experimental purposes and possibly also for therapeutic use.

## Inhibition of Adenosine Diphosphate-Induced Platelet Aggregation by Histamine

It is now well known that adenosine and adenosine monophosphate (AMP) strongly inhibit the aggregation of human and rabbit platelets which occurs in the presence of adenosine diphosphate (ADP). Adenosine and AMP are effective at a concentration of approximately 10<sup>-7</sup> M, and are the most potent naturally occurring inhibitors known. O'Brien<sup>1</sup> has shown that antihistaminics, anti-malarials, and local anaesthetics, all at approximately

Fig. 1. Inhibition of ADP-induced platelet aggregation. At zero time 10<sup>-4</sup> M ADP was added to rabbit platelet-rich plasma which had been incubated 1 min with: A, 0.9 per cent sodium chloride solution; B, histamine, 5 × 10<sup>-3</sup> M; C, histamine, 10<sup>-3</sup> M; D, histamine, 10<sup>-4</sup> M; E, adenosine, 10<sup>-3</sup> M.

10<sup>-3</sup> M, inhibit ADP-induced platelet aggregation. It has recently been reported by Salzman and Chambers<sup>2</sup> that substituted amino-acids, at a concentration of 1.5 × 10<sup>-4</sup> M, inhibit ADP-induced platelet aggregation.

It has now been found that histamine inhibits ADP-induced aggregation of rabbit platelets. Changes in light transmittance of platelet-rich plasma on addition of ADP were recorded at 23° C, as described by Born<sup>3</sup> and O'Brien<sup>4</sup>. Fig. 1 shows the inhibitory effect of various concentrations of histamine when this was added to the plasma 1 min before the addition of ADP; all concentrations are final concentrations in the test system. The results were similar when histamine remained in contact with the plasma for 10 min prior to the addition of ADP; but when histamine was incubated with plasma for 30 min at 37° C, then cooled rapidly to 23° C, there was no inhibition of ADP. This may be explained by the action of plasma histaminase during the 37° C incubation period; in addition, it has been shown that there is increased platelet responsiveness to ADP in platelet-rich rabbit plasma which has been incubated at 37° C, and then cooled rapidly to 23° C<sup>5</sup>. Imidazole (10<sup>-3</sup> M) did not inhibit ADP-induced platelet aggregation. A series of substituted imidazoles, each tested at 10<sup>-3</sup> M, were ineffective as inhibitors of ADP:

2-aminoimidazole      β-(N,N-dimethylaminoethyl)imidazole  
2-methylimidazole      4-(β-n-propylaminoethyl)imidazole  
2-mercaptoimidazole      4-(β-isopropylaminoethyl)imidazole  
4,5-imidazoledicarboximorpholide      4-(β-butylaminoethyl)imidazole  
2-n-butylmercaptoimidazole      4-(β-di-n-butylaminoethyl)imidazole

O'Brien<sup>6</sup> has reported that histamine does not inhibit ADP-induced aggregation of human platelets, and this may be yet another example of species-determined differences in the behaviour of platelets toward both aggregating agents and their inhibitors. There is no obvious explanation of the mechanism by which histamine inhibits ADP-induced platelet aggregation. Butcher and Sutherland<sup>7</sup> have shown that imidazole stimulates cyclic phosphodiesterase, the enzyme which converts cyclic 3',5'-AMP to AMP. It is possible, therefore, that histamine might stimulate cyclic phosphodiesterase and so result in the production of an inhibitory level of AMP. Evidence against this concept is the lack of inhibition to ADP-induced platelet aggregation by imidazole.

## Molecular Support of Rheumatoid Factor and Anti-Gm(a) Activity

A SPECIFIC serological activity was found several years ago in the serum of patients suffering from rheumatoid arthritis.

This rheumatoid factor (RAF) has been localized in the 19 S- $\gamma$ -globulin<sup>1</sup>. Grubb and Laurell<sup>2</sup> found a second serological activity in certain arthritis sera (Ragg) causing the agglutination of human red blood cells coated by selected incomplete anti-D sera. This factor has been called anti-Gm activity as it allows the detection of the different  $\gamma$ -globulin (Gm) groups. The anti-Gm activity is also associated with the  $\gamma$ -19 S group, so the question arises whether Ragg-serum containing both RAF- and anti-Gm(a) activity has 12 different serologically active populations or whether these activities are associated with the same molecular support.

Steinberg<sup>3</sup>, while studying this problem with the F II-latex-fixation test, stated that Ragg-serum with both RAF and anti-Gm(a) activity contains two distinct  $\gamma$ -19 S populations: one with RAF activity alone and the other with both RAF- and anti-Gm(a) activity. Harboe<sup>4</sup>, on the other hand, postulated that Ragg-serum with both serological activities contains two populations: one with RAF activity and the other with anti-Gm(a) activity. These results were obtained by the specific adsorption of RAF activity on sheep red blood cells coated with rabbitamboceptor.

While working on the isolation of the molecular support of anti-Gm(a) activity we found that anti-Gm(a) activity from normal serum can be adsorbed specifically on diazotized *p*-aminobenzylcellulose coupled with Gm(a<sup>+</sup>)- $\gamma$ -globulin<sup>5</sup>.

The same support has been found suitable for the dissociation of anti-Gm(a) and RAF activities in Ragg.

The chemical attachment of human  $\gamma$ -globulin to the insoluble cellulose derivative gives a better reagent than the simple adsorption of the protein on latex particles (polystyrene resin) which is more or less reversible. Pure  $\gamma$ -globulin of Gm(a<sup>+</sup>) as well as Gm(a<sup>-</sup>) serum has been prepared by a technique combining the precipitation of most of the serum proteins with rivanol and adsorption of the remaining impurities on DEAE cellulose.

The following complexes have been prepared: (A) PAB- $\gamma$  Gm(a<sup>+</sup>); (B) PAB- $\gamma$  Gm(a<sup>-</sup>); (C) PAB- $\gamma$  Gm(a<sup>+</sup>), heated; (D) PAB- $\gamma$  Gm(a<sup>-</sup>), heated. In the case of the heated preparations, the solution of  $\gamma$ -globulin (1 per cent) was heated for 10 min to 63° C before combination with the diazotized PAB-cellulose.

The unspecific adsorption of RAF on heat-aggregated  $\gamma$ -globulin is a well-known phenomenon. Initially we supposed that anti-Gm(a) activity would only be adsorbed by complex (A) and eventually by complex (C), whereas RAF would be adsorbed by (C) and (D).

However, we soon realized that these complexes have a considerable non-specific affinity for both activities. We therefore enquired whether there exists an important quantitative difference between the specific and the non-specific adsorption of anti-Gm(a) activity by adsorbing different Ragg sera with complexes (A) and (B). Under optimal conditions, using a minimal amount of complex, about 90-100 per cent of anti-Gm(a) will be adsorbed to complex (A), and less than 10 per cent to complex (B), the latter being used as a control to evaluate 'non-specific adsorption'. Such small differences cannot be detected by ordinary serological techniques and we had to do this quantitation by photometric titration<sup>6</sup>. It was evident that the non-specific adsorption of anti-Gm(a) to PAB- $\gamma$ -Gm(a<sup>-</sup>) could be very small (less than 10 per cent) under appropriate conditions.

However, the titration of RAF activity in the supernatant of complex (A) showed a loss of about 25 per cent. It is conceivable that RAF has a greater non-specific affinity for the cellulose-protein complexes than have the

anti-Gm molecules, and the loss of 25 per cent of its activity could be explained by non-specific adsorption. However, complex (B), which adsorbed about 10 per cent of anti-Gm(a) activity (non-specific) did not modify the titre of RAF activity. It is therefore probable that the part of RAF adsorbed together with the total activity of anti-Gm(a) shares a common molecular basis with anti-Gm(a) and that its adsorption is mediated by the specific adsorption of anti-Gm(a) to PAB-Gm(a<sup>+</sup>). The observations therefore suggest that there are two different populations, one of which has both activities, whereas the other has RAF activity alone, as 75 per cent of RAF remains in the adsorbed serum. We found that anti-Gm(a) has a greater affinity (non-specific adsorption) for all the complexes used, so it was not possible to use this system for the adsorption of RAF leaving anti-Gm(a) in the supernatant.

Evidence of a third population, with anti-Gm(a) activity alone, was provided by the adsorption of RAF activity on human red cells sensitized by rabbitamboceptor. Using the photoelectric titration method we found that 50 per cent of anti-Gm(a) activity disappears together with all the RAF activity.

The concomitant adsorption of 50 per cent of the anti-Gm(a) activity, however, was not due to non-specific adsorption. Indeed, the serum devoid of RAF activity and of 50 per cent of anti-Gm(a) activity after this first adsorption has been reabsorbed by an identical quantity of sensitized red cells and the anti-Gm(a) titre was unchanged (50 per cent of the original titre) after the second adsorption. These observations thus revealed two populations: one having RAF activity as well as anti-Gm(a) activity, the second having anti-Gm(a) activity alone. Different Ragg-sera submitted to both tests gave similar results. The exact quantitation for one of our sera revealed that 25 per cent of the RAF activity had a common basis with about 50 per cent of anti-Gm(a) activity whereas 75 per cent of RAF and 50 per cent of anti-Gm-activity had an independent molecular support. Further details will be published elsewhere.

## Apparent Interaction Between the Xg<sup>a</sup> Blood Group System and the Sex Ratio: A Note of Explanation

PROF. J. H. BENNETT has called to our attention a possible source of confusion in our recent letter<sup>1</sup>. We left implicit the assumption that the expected sex-ratios in the two classes, 'Before and including the first female', and 'After the first female', were equal, and we failed to make clear that the numbers of children in our Table 1 included those from all-male sibships. If such sibships had been omitted, the sex ratio (male:female) would indeed have been expected to be higher in the first class than in the second, but when they are included, as was done, the expected ratios are equal. Other explanations of our

observation, such as selective family limitation, do not account for its limitation to the single Xg—Xg<sup>a</sup> mating type where the postulated 'incompatibility' could occur.

## HISTOCHEMISTRY

### Fixation In Enzyme Histochemistry

Use of unfixed frozen sections is confined to enzymes extremely sensitive to denaturation such as the dehydrogenases. Most authors on the subject state or imply that the method introduces the disadvantages of (1) mechanical disruption by freezing and thawing, (2) reduction in quality of tissue detail, (3) uneven section thickness, (4) diffusion of soluble enzymes and co-factors leading to loss of reproducibility and false localization, and (5) inability to cut serial sections<sup>1-4</sup>. These disadvantages are said to outweigh the advantages of high specificity and activity, and simplicity of preparation. The alternative method of briefly fixing sections overcomes many of these disadvantages at the expense of possible alteration in specificity and activity.

The method described and evaluated here is suitable for all enzyme histochemical procedures and makes a better compromise between the conflicting demands of activity, freedom from artefact and quality of section.

Fresh-frozen sections were cut on a cold knife freezing microtome by a modified Adamstone-Taylor technique<sup>5</sup>. The section was manipulated with a squirrel-hair brush (previously dipped in a 5 per cent dimethyl polysiloxane solution—Dow Corning Corp. '1107'—dried and wiped free of excess siloxane), picked directly from the microtome blade onto a slide, and allowed to dry. The siliconed brush overcame the tendency of bristles to stick to tissue, resulting in easier handling. Serial sections of constant

thickness could be readily cut in the high ambient temperature of an Australian summer. Paired sections of rat and mouse tissue prepared by this technique were treated as follows: (1) One of each pair was incubated in standard substrate solutions for a wide variety of enzymes; it was then passed directly for 1 h to a fixing solution in which the dye precursor was insoluble, and staining was completed by the appropriate methods. Details of methods and results are set out in Table 1.

The quality of detail in the sections, and the staining, was satisfactory, and clouding of the substrate solutions, indicating diffusion of enzyme from the incubating section, was not seen. It was therefore assumed that diffusion of this type had not occurred. (2) The other section of each pair was fixed in an accepted histochemical fixative for periods of 5, 10, 20, 40 or 60 min, rinsed and then incubated and stained as in procedure (1). Details of methods and results are set out in Table 2. Enzyme activity was judged by eye against that of the unfixed sections in Table 1.

Sections fixed after incubation were in all respects better than those fixed before. They were free of stretching, shrinking or other artefacts of handling and showed no tendency to lift from slides even during 2 h incubation. Efficiency of subsequent steps was not disturbed and diffusion beyond the cell or into the nucleus did not occur. There was nothing to suggest false localization of hydrolysed products. All results were reproducible. No effect of mechanical disruption by freezing could be detected at the histological level. The optical quality of sections was comparable with those cut from paraffin blocks.

In contrast, most sections fixed before incubation showed significant loss of activity when fixed for the minimum time necessary to ensure even penetration of fixative. Diffusion of enzyme, giving false localization, also occurred. Optical quality of sections was inferior except when aqueous formalin had been used as fixative. These changes in activity, diffusion and optical quality were individual and not distributed in any pattern. No fixative could be described as satisfactory for the range of enzymes tested against the parameters used. Fixation after incubation in substrate is therefore recommended for general use in enzyme histochemistry.

Table 1. DETAILS OF METHODS USED ON FROZEN SECTIONS FIXED AFTER SUBSTRATE INCUBATION

Enzyme and method of incubation	Fixation (for 1 hour)	Subsequent handling

## HISTOLOGY

### Demineralization of Bone

DEMINERALIZATION of specimens for the preparation of histological sections is a time-consuming process. Mineral acids demineralize the specimens faster than chelating agents or organic acids, but the resultant distortion in cellular morphology is greater when mineral acids are used. The rate of demineralization depends mainly on the temperature and concentration of the acid, but since cellular definition and enzymes are adversely affected if the temperature is raised, or when the concentration of the acid is increased, demineralization is usually carried out below or at room temperature and a concentration of mineral acid above 5 per cent of commercial nitric acid (55 per cent) is seldom used. Under these conditions even small specimens of bone must be immersed in acid for days before they are completely demineralized. For teeth, the period of time runs into weeks.

The whole process of demineralization can be reduced to hours, even minutes, if ultrasonic energy is propagated through the demineralizing solution. Subsequent sectioning of the specimen with a freezing microtome, in a cryostat, or as paraffin-embedded sections all produce preparations in which the cellular detail is superior to those seen in similar specimens treated with the same mineral acid for longer periods of time. All soft tissue detail is improved, but the most significant improvement in cellular morphology is seen in the chondrocytes and osteocytes.

In these preliminary experiments a Disontegrator system 80' with a frequency of 90,000 per sec was used. The temperature of the water in the tank was controlled by a constant exchange of the tank water from the cold-water supply. The best results were obtained when the demineralizing fluid and fixed specimens were placed in a large beaker immersed in the partially filled tank directly over the crystal. To prevent damage to the tank, sodium bicarbonate was added to the water in it and the beaker was covered to prevent spattering of the agitated acid.

Nitric acid at a concentration of 2.5, 5 or 10 per cent was used in these experiments and the acid solutions were changed every half-hour. Although it is not possible to

indicate an optimum concentration of the nitric acid at this stage, the more rapid decalcification in the 10 per cent solution of nitric acid seemed to produce less cellular distortion in the sections.

The time taken to demineralize a specimen is affected not only by the degree of mineralization, but also to a marked degree by the amount of investing soft tissue. When an adult rat femur is divided into three segments and 10 per cent acid is used, decalcification can be accomplished in less than 2 h. Without the investing soft tissue demineralization is complete within 1 h.

When haematoxylin and eosin are used the time taken to stain sections decalcified in this manner is considerably reduced and the differential staining of the various tissues is more selective.

### Histology of the Posterior Chamber of the Swimbladder of *Argentina*

*Argentina* was the first genus among the salmonoid fishes in which the swimbladder was reported to lack an open communication with the oesophagus, typical for the sub-order Salmonoidae<sup>1,2</sup>. This has since been found to apply also to the families Microstomidae and Opisthoproctidae<sup>3</sup>. A more detailed description of the structure of the swimbladder of *Argentina silus*<sup>4</sup> revealed the occurrence of a large number of flat bundles of blood vessels, which constitute a counter-current system. The name micro-retia mirabilia<sup>5</sup> has been established for this type of rete mirabile. In *Argentina* a gas gland tissue was also detected<sup>6</sup>, being in contact with capillary loops from the micro-retia. From these findings it was concluded that the swimbladder of *Argentina silus* has a capacity for gas secretion comparable to the swimbladder with a rete mirabile of the compact type.

A thin sac at the caudal end of the swimbladder of *Argentina sphyraena* has been briefly described and suggested to be a posterior chamber<sup>7,8</sup>. Observations also argue that it might have a resorbent function<sup>9</sup>. The draining vessels were seen to be a part of the hepatic portal system<sup>9</sup>.

The present investigation was intended to produce histological evidence for a supposed resorbent function of the posterior chamber of the swimbladder. Several specimens of *Argentina silus* and *A. sphyraena* were caught off the west coast of Norway at the Biological Station of the University of Bergen. The animals were brought to the surface (200 metres depth to surface in 20 min). The swimbladder in most of them had not burst—an occurrence often reported in captured specimens of *Argentina*. The animals could be kept in aquaria for 6–10 h after capture. The posterior sac of the swimbladder was observed. Longitudinal and transverse sections, fixed in Bouin's fluid, were stained with Azan, and the morphology and histology of the posterior part of the main chamber and the posterior thin-walled sac were investigated. Swimbladders from some specimens were, immediately after killing, freeze-dried, treated with formaldehyde gas for 1 or 3 h at 80° C, and then infiltrated with paraffin *in vacuo* in order to condense catecholamines and 5-hydroxytryptamine to fluorescent products<sup>10</sup>. They were then investigated under a fluorescent microscope in dark-field illumination.

It was confirmed that the posterior sac constitutes a posterior chamber of the swimbladder in communication with the anterior part of the organ. It is not separated from the anterior chamber by a membrane with a central opening and possessing a radial muscle, as is normal in

other two-chambered swimbladders. The lumen of the anterior chamber gradually decreases in diameter and passes into the opening that leads to the posterior chamber (Fig. 1). The opening is surrounded by a circular muscle, which apparently constitutes a sphincter. This muscle is coherent with a rather thick circular muscle layer, which is an important part of the wall of the posterior chamber. It is in turn surrounded by a longitudinal muscle layer formed by more or less separate muscle bundles. The anterior parts of these longitudinal muscle bundles were seen to be attached to the sphincter muscle. Outside the muscles is a layer of connective tissue, lodging about ten big vessels, both arteries and veins. The arteries originate in one single vessel—a branch of the intestinal artery—and enter the organ at its posterior, forward-bent end. The veins leave the organ as 5–8 separate vessels but soon join into one, which is a branch of the hepatic portal system. No connexion could be traced between the vessels of the posterior chamber of the swimbladder and those of the anterior chamber.

The arteries in the submuscular connective tissue layer of the posterior chamber branch into a number of smaller vessels that traverse the muscle layers and enter a layer of loose connective tissue inside the muscles. By repeated division, the arteries there give rise to a capillary network in close contact with an epithelium, composed of flat to cubical cells, that forms the lining of the lumen. The capillaries recombine into venous vessels, which unite into the big veins mentioned above.

An investigation of the occurrence of catecholamines and 5-hydroxytryptamine, in order to localize the sympathetic nerves of the organ, revealed the following: After treatment for 1 h at 80° C, a green fluorescence was seen in

the anterior chamber between the muscle layer and the underlying gas gland tissue (Fig. 2). This indicated the presence of a primary catecholamine, possibly noradrenaline. It was located in a network of longitudinally arranged, smooth, preterminal nerve fibres, which were seen to give rise to intensely green-fluorescent, fine, varicose nerve-endings. No fluorescent fibres were seen to intermingle with the muscle fibres or with the gas gland cells. This fluorescent network was distributed over the whole anterior chamber. In the posterior chamber intensely green-fluorescent, varicose, terminal nerve fibres were abundant in the muscle layers. In the border region between the longitudinal muscles and the submuscular connective tissue, longitudinal bundles of smooth, preterminal nerve fibres were seen. In this region, there was also a relatively abundant occurrence of ganglion cell bodies with a moderate green fluorescence, giving rise to the preterminal and terminal fibres already mentioned. A number of bundles of smooth, preterminal nerve fibres were seen to reach the opening to the anterior chamber. They most probably give rise to the network of fibres found in this chamber.

There seems to be no doubt of the accuracy of the opinion of earlier authors<sup>1,2</sup> that the caudal, thin-walled sac is a posterior, resorbent chamber of the swimbladder. The present investigation shows that this sac has all the morphological characteristics of an organ with a gas-resorbent function. It is connected with the anterior chamber by an orifice that possesses a muscular sphincter which is apparently able to close the opening completely. The sphincter muscle is part of the muscular coat of the posterior chamber, which muscle system will when contracted decrease the luminal volume of this chamber and also close the orifice. When relaxed, this muscle will allow the orifice to open, give the chamber its maximal volume, and allow a maximum of blood to reach the base of the epithelium. The mucosa is very richly vascularized, and the vessels have no connexion with those of the anterior chamber. The sphincter muscle and the muscle layers of the posterior chamber seem to be sympathetically innervated, which is not the case with the musculature of the anterior, secretory chamber. Concerning the fluorescent nerves found in the anterior chamber, there is reason to believe them to innervate some part of the gas-gland tissue, since the musculature of this chamber is presumably antagonistically innervated to the muscles of the posterior chamber. Further investigation, however, is necessary to clarify this point.

## PATHOLOGY

### Polyuridylic Acid Stimulation of Phenylalanine in Human Ribonucleoprotein Particles

THE discovery that synthetic polynucleotides can direct the incorporation into protein of specific amino-acids in cell-free bacterial systems<sup>1,2</sup> has been extended to include sub-cellular systems in rat liver<sup>3</sup>, and mouse plasma cell tumour<sup>4</sup>, where coding units for amino-acid incorporation were found to be similar to the *Escherichia coli* system. Weinstein and Schechter<sup>4</sup> also reported polyuridylic acid (poly U) stimulation of phenylalanine incorporation into crude cell-free fractions of normal mouse and rat livers,

Fig. 1. *Argentinus silus*, swimbladder. The posterior end of the anterior chamber (right) and the anterior part of the posterior chamber (left). The section is not exactly median and the circular muscle of the sphincter is visible where the two chambers meet ( $\times 630$ ).

Fig. 2. *Argentinus silus*, swimbladder. Green-fluorescent nerve fibres in the anterior chamber. The nerves form a plexus between the muscle layer (next to the black lumen) and the gas gland tissue ( $\times 820$ ).

a rat liver tumour, rabbit reticulocytes and a human plasma cell tumour. The experiments reported here support the applicability of this type of study to various human tissues. Poly U was found to stimulate the incorporation of phenylalanine into ribonucleoprotein (RNP) particles of human liver, ovary, lung and prostate. Rat liver RNP preparations are similarly stimulated.

Seventy-five g human liver was obtained from each of two autopsies. The liver samples were available 4-5 and 16 h post-mortem and were free of gross and microscopic pathology. Comparable results were obtained with each of the two liver samples. Human lung (33 g), human ovaries (8 g), and human prostate (15 g) were obtained within 1 h of surgical removal in various operative procedures. The lung sample was from an area far removed from the proximal segment of lung involved with epidermoid carcinoma. Our sample was microscopically free of tumour involvement. The ovaries were part of a total hysterectomy block in which the only pathology was uterine fibroids. The prostatic tissue was from a patient suffering from benign prostatic hypertrophy. The rats were Columbia Sherman males weighing approximately 150 g and the mice were 6-week-old C57BL males.

RNP particles were prepared by a modification of the procedure of Rendi and Hultin<sup>8</sup>. Tissues were trimmed of capsule where necessary and then minced and rinsed 3 times with equal amounts (w/v) of ice-cold homogenizing solution (tris-HCl 0.034 M, pH 7.8, potassium chloride 0.02 M, magnesium chloride 0.01 M, and sucrose 0.2 M).

All subsequent procedures were performed at 4°C. The human tissues were homogenized with 1.5 volumes of homogenizing solution with a 'Model 43' Virtis homogenizer for 2 min at 40,000 r.p.m. The rat and mouse livers were homogenized with 1.5 volumes of homogenizing solution in a glass homogenizer fitted with a 'Teflon' pestle for 45 sec at approximately 1,500 r.p.m. All homogenates were centrifuged at 12,000g for 10 min. Aliquots of the resulting supernatant (S-12) were centrifuged for 2 h at 105,000g to obtain the supernatant (S-105) fraction. The remaining S-12 supernatant was added to 1/20 volume of 10 per cent 'Lubrol W'. A volume of 10 per cent sodium deoxycholate equal to the 'Lubrol W' was added with stirring. The resulting suspension was layered in 'Lusteroid' centrifuge tubes on an equal volume of layering solution (tris-HCl 0.034 M, pH 7.8, potassium chloride 0.6 M, magnesium chloride 0.01 M and sucrose 0.3 M), and centrifuged for 2 h at 105,000g. The resulting clear pellet of RNP (P-105) was rinsed 3 times with suspending solution (tris-HCl 0.01 M, pH 7.8, potassium chloride 0.2 M, and magnesium chloride 0.01 M). The outer layers of the RNP pellets were carefully dislodged and suspended in a few ml. of suspending solution and homogenized in small all-glass homogenizers for 15 sec. Protein was determined by the biuret method<sup>9</sup>. 'Lubrol W' was obtained from Arnold Hoffmann and Co., Providence, R.I., and the homopolymers from Miles Laboratories. The *in vitro* reaction system and method of handling of samples for isotopic counting is given in Table 1.

Poly U results in up to a fifty-fold stimulation of phenylalanine incorporation by RNP of rat liver, and human ovary, prostate, lung and liver (Table 1). With the exception of the rat and human liver RNP preparations, those experiments in which poly U stimulation was noted, included a heterologous source of amino-acid activating enzymes and soluble nucleic acid fractions (S-105 fraction). Autologous and homologous S-105 fractions were inactive in these experiments. Poly U enhanced phenylalanine incorporation by human liver RNP preparations regardless of the S-105 source. Other homopolymers did not stimulate phenylalanine incorporation into the human liver RNP system.

Apart from a brief report on a human plasma cell tumour<sup>4</sup>, in which relatively crude supernatant fractions were used, the experiments reported here are, to our

Table 1. POLYURIDYLIC STIMULATION OF PHENYLALANINE INCORPORATION INTO RAT AND HUMAN RIBONUCLEOPROTEIN PARTICLES

Ribonucleoprotein (P-105)	Polynucleotide addition	Supernatant (S-105)	cpm of alanine/mg RNP protein
Rat liver	None	Rat liver	80

Human liver	+40 µg Poly U	Rat liver	20
Human liver	+40 µg Poly U	Rat liver	20
Human liver	None	Human liver	10
Human liver	+40 µg Poly U	Human liver	125

The complete reaction mixture was contained in a total volume of 0.65 ml. It contained the following components (in  $\mu$ moles unless otherwise specified): Tris-HCl buffer, pH 7.8, 22.4; MgCl<sub>2</sub>, 8.0; KCl, 50.0; mercaptoethanol, 5.0; ATP, 0.8; creatine phosphate, 8.0; creatine phosphokinase, 40 µg; GTP, 0.2; 'Lubrol', 0.8 mg; a mixture of <sup>14</sup>C-L-amino acids excluding phenylalanine, 0.004 of each, and <sup>14</sup>C-L-phenylalanine ( $\phi$  alanine), 25  $\mu$ moles, sp. act. 10-3 mCi/mM (about 25,600 c.p.m.).

As specified, 40 µg of the potassium salts of polyuridylic (poly U), polyadenylic (poly A), polycytidylic (poly C), polynucleic (poly I) acids and the equivalent of 1-4 mg of S-105 protein and 0.5-1.5 mg of P-105 protein were added per reaction mixture.

Samples were incubated at 37°C for 45 min, deproteinized with 10 per cent trichloroacetic acid (TCA). The precipitates were washed once with 10 per cent TCA, and heated twice for 15 min each time with 5 per cent TCA at 90-95°C, plated and dried with ethanol and ether on a 'Tracerlab' precipitation apparatus and counted in a gas flow counter with an error of less than  $\pm 2$  per cent. Samples were corrected for self-absorption and for reagent control blanks.

knowledge, the first to demonstrate polynucleotide-stimulated amino-acid incorporation by RNP preparations from human tissue. The nature of this stimulation in human tissue supports the concept of universality for the genetic code previously surmised from work in other mammalian<sup>3,4</sup> and bacterial and viral systems<sup>7-10</sup>. We are now defining the human tissue RNP system in terms of its requirements and inhibitors and studying the effect of homologous and heterologous ribonucleic acid preparations on amino-acid incorporation by normal and diseased human tissue RNP preparations<sup>11</sup>.

### Electron-microscopic Demonstration of Bacteria in the Skin of Patients with Lichen Ruber Planus

THE aetiology of lichen ruber planus is uncertain. A number of hypotheses have been advanced<sup>1</sup>. Lichen ruber planus eruptions have been observed in connexion with the use of different drugs, for instance atabrin. In

Fig. 1. Groups of bacteria (arrows) within the dilated interspace in the deeper part of the epidermis ( $\times 4,500$ )

Fig. 2. Higher magnification of longitudinally and transversely sectioned bacteria. 1 and 2, outer membrane and intermediate layer, respectively, of the cell wall; 3, inner membrane or plasma membrane; 4, less opaque layer between the plasma membrane and the granular cytoplasm; r, ribosomes; N, nuclear apparatus with fibrous material; v, vesicle ( $\times 84,000$ )

these cases, however, it has not yet been determined whether it is a matter of a genuine lichen or of a lichenoid dermatosis. In cases in which a relation to drugs is out of the question two main possibilities have been put forward, namely, those of an infectious or a nervous aetiology. Conclusive proof for any of these theories has not yet been presented. As infectious agents, viruses and spirochaetes have been suggested. The therapeutic success attained in some cases with chemotherapeutics and antibiotics has been adduced as an argument in favour of an infectious aetiology<sup>1</sup>.

During the course of electron-microscopic investigations of skin eruptions in lichen ruber planus, pictures have been obtained which indicate the presence of bacteria within and around capillaries in the stratum papillare of the dermis and between the cells in the deeper part of the epidermis. A report on this finding will be given below.

In skin affected by lichen ruber planus from four patients cells of the type seen in Fig. 1 were found. They appear singly or in small groups, irregularly distributed throughout the tissue. The cells are rod-shaped and have a length of approximately  $1.3\mu$  and a breadth of approximately  $0.4\mu$ .

The cells are bounded by an envelope having a total thickness of  $240\text{--}280\text{ \AA}$ . Three sub-layers are distinguished within the envelope: an outer and an inner membrane, displaying a triple-layered pattern, and an intermediate, single layer (Fig. 2). The outer membrane has a wavy course and usually shows a higher opacity than the inner membrane. Its total width is  $90\text{--}100\text{ \AA}$ . The intermediate layer has a low opacity and varies between  $60$  and  $100\text{ \AA}$  in breadth. The inner membrane encloses the protoplasm of the cell and is  $80\text{--}90\text{ \AA}$  wide.

The protoplasm consists of a granular and a fibrous component (Fig. 2). The granular substance is found mainly within a zone along the periphery of the cell. This zone is separated from the inner membrane of the envelope by a narrow, less-opaque layer (Fig. 2). The granular substance contains fairly opaque particles ranging between  $80$  and  $200\text{ \AA}$  in size.

The opaque, fibrous material occupies for the most part the central area of the cells, which displays a low electron density (Fig. 2). This area is not bounded by any membrane, but there is direct contact between the fibrous and granular substances. Fine filaments with a thickness of  $20\text{--}30\text{ \AA}$  and thicker fibrous strands varying between  $100$  and  $250\text{ \AA}$  are observed in the same cell. Occasionally filaments of the finer diameter may be discerned within the strands. The filaments and fibrous strands form a continuous, irregular network.

Within the area of low electron density a varying number of vesicles occur. They vary from  $840$  to  $1580\text{ \AA}$  in length and from  $730$  to  $1580\text{ \AA}$  in breadth. The vesicles are bounded by a triple-layered membrane (Fig. 2).

The cell described here is with respect to size, shape and ultra-structure consistent with the description of bacteria. The envelope of the cell shows the same breadth and ultra-structural arrangement in sub-layers as has been described for several Gram-negative bacteria<sup>2-4</sup>. Thus, in accordance with these investigations on Gram-negative bacteria, the inner membrane of the envelope will here represent the plasma membrane of the cell, whereas the intermediate layer and the outer membrane together form the cell wall. As is the case with bacteria belonging to the family Caulobacteraceae<sup>5</sup>, the outer membrane of the cell wall in the present study displays a wavy course.

A narrow, less-opaque layer between the plasma membrane and the granular substance of the protoplasm has been observed by me. In *Staphylococcus aureus* a similar layer has been described, being attributed to the cytoplasm as the cytoplasmic matrix<sup>7</sup>.

The protoplasm of the cell reported here exhibits an arrangement characteristic of bacteria with a nuclear apparatus consisting of a network of fibrous material within a less electron-dense area and in direct continuity with the granular cytoplasm<sup>2-4</sup>. The fibrous substance of the nuclear apparatus is considered to represent the deoxyribonucleic acid portion of the chromatin material<sup>2,4,8,9</sup>. The opaque particles of the granular cytoplasm are of the same size as has been reported in earlier studies and are thought to represent ribosomes<sup>2,4</sup>.

The observations reported here may thus justify the interpretation of the occurrence of bacteria in lichen ruber planus eruptions. No bacteria have hitherto been described in electron micrographs of skin<sup>10-12</sup>. The demonstration of bacteria in skin biopsies from four out of five lichen ruber planus patients appears to rule out the possibility of an incidental finding. Furthermore, the tissue lodging the bacteria exhibits consistent dermal and epidermal changes in all cases (to be published).

In frozen histological sections of lichen ruber planus eruptions Lennhoff<sup>13</sup> showed structures which he assumed to be spirochaetes. The bacteria found in the present investigation are considerably shorter in length than the structures described by Lennhoff.

Further investigations are being carried out to elucidate the frequency of the bacteria in a larger case material, to

attempt to identify the type here observed and to ascertain whether it plays any aetiological role and, if so, whether it alone may be responsible for eruptions of lichen ruber planus type or whether more factors are implied.

## IMMUNOLOGY

### An Alpha<sub>2</sub>-globulin Component Absent in Serum of Human Foetuses

WHEN studying specific antigenic properties of sweat proteins using rabbit immune serum against sweat proteins, we have found sweat protein to consist of several components, some of which correspond to serum components whereas the others are most probably of a specific origin<sup>1,2</sup>. In an attempt to define the serum protein components in sweat, immunoelectrophoresis of normal human serum with rabbit-immune serum against sweat proteins was one of the methods used. In these experiments we observed qualitative differences in the immunoelectrophoretic precipitation pattern of a normal serum of adults in comparison with that of foetuses.

The immunoelectrophoretic precipitation pattern of a normal serum of adults using rabbit immune serum against

sweat proteins is marked by several precipitation lines, the strongest of which is localized in an alpha<sub>2</sub>-globulin zone; this precipitation line was found not to be present in the serum of foetuses (six foetuses, gestation age 18-24 weeks, Fig. 1).

On saturating the rabbit immune serum against sweat proteins with normal serum from adults, no precipitation reaction was found in the latter (Fig. 2); when the rabbit immune serum was saturated with a serum of foetuses, only the alpha<sub>2</sub>-globulin component was marked in the immunoelectrophoresis precipitation pattern of a normal serum of adults (Fig. 3).

Fig. 2. Immunoelectrophoretic patterns of normal serum of adults (1, 2, 3, 4) using rabbit immune serum against sweat proteins with (in the second and fourth longitudinal basin) and without saturation with normal serum of adults.

Fig. 3. Immunoelectrophoretic patterns of normal serum of an adult (1, 3) and of that of a foetus (2, 4) using non-saturated rabbit immune serum against sweat proteins with serum of foetuses (in the first, third and fifth longitudinal basin) and saturated with serum of foetuses 10:1 (in the second longitudinal basin) and 10:2 (in the fourth longitudinal basin).

Fig. 1. Immunoelectrophoretic patterns of normal serum of an adult in comparison with that of a foetus. 1, Normal serum of an adult; 2, serum of a foetus (in longitudinal basins horse immune serum against normal human serum); 3, serum of the same adult; 4, serum of the same foetus (in longitudinal basins rabbit immune serum against sweat proteins).

Using a double-diffusion technique in Ouchterlony gel<sup>3</sup>, a weak deviation of the end of the precipitation line corresponding to alpha<sub>2</sub>-globulin component in serum of adults was observed in foetal serum.

At present we are studying in detail the character of this alpha<sub>2</sub>-globulin component in serum, which, according to its immunoprecipitation intensity with anti-sweat protein immune serum, does not seem to correspond to any other alpha<sub>2</sub>-globulin component present in immunoelectrophoretic precipitation patterns of normal human serum, when a polyvalent immune serum against serum proteins is used. The details of the occurrence of this alpha<sub>2</sub>-globulin component in human serum during ontogenesis

(especially in new-borns and in babies in the first weeks after birth) will be published later.

## RADIOBIOLOGY

### Modification of Radiation-Induced Injury in Barley by Pre-treatments with Solutions of different Osmotic Potential

It has already been shown<sup>1,2</sup> that the growth of the coleoptile and first leaf from barley seeds soaked prior to irradiation in 0.5 molar solutions of sodium and alkaline-earth chlorides is greater than that of controls soaked in distilled water. This radioprotection is provided by different salts not specially recognized as inducing such effects (magnesium chloride excepted)<sup>3</sup>. It has therefore been assumed that the mechanism of this reduction of X-ray damage is an indirect one. The physiological effects relating to the osmotic potential of the soaking solutions were proposed to explain the results obtained.

This communication presents new evidence in favour of this hypothesis which will be considered with increasing osmotic potential of a solution of calcium chloride in which seeds were soaked.

The barley seeds (caryopses of *Hordeum sativum* Joss. var. *pirolina*) were provided by the Institut agronomique de Gembloux. Before the irradiation the seeds are soaked for 12 h at room temperature in the solutions of calcium chloride (Calcium chloratum fustum sur Elementaranalyse, Merck), neutralized by hydrochloric acid (pH about 6.9), washed three times with distilled water and rapidly blotted. The molecular concentrations of calcium chloride solutions are 0.05, 0.25, 0.5, 1, 1.5, 3 and 4 M. The X-rays generated from a Siemens 'Stabilipan', operated at 140 kV and 20 m.amp are filtered through 2 mm of aluminium. The seeds lie in a single layer in an uncovered Petri dish on a rotating turntable 15 cm from the target; the dose rate is 1,000 r/min. In different experiments the total dose varied from 0.25 to 12 krad. Immediately after irradiation, all seeds were placed on moist germination paper in Petri dishes and grown in a controlled-environment room (16 h photoperiod;  $24^{\circ} \pm 1^{\circ} \text{C}$ ). Groups of 50 seeds were used for each dose replicated three times. For each treatment the lengths of the coleoptile and the first leaf were measured, averages taken and expressed in per cent of the non-irradiated controls. The osmotic potentials of the soaking solutions were calculated from the osmotic coefficient of calcium chloride tabulated by Robinson and Stokes<sup>4</sup> after transformation of molecular concentrations in molar concentrations.

There is a linear relationship between the osmotic potential of the calcium chloride solutions and the moisture content of the barley seeds, except for the lowest concentration (Fig. 1). The irradiation reduces the length of the coleoptiles and the first leaves: typical sigmoidal curves against dose are obtained. There is no difference between the seedling issued from seeds pretreated in 0.05 M calcium chloride solutions or soaked in distilled water. But with increasing molar concentration, the damage by X-rays for a given dose is reduced. The maximum protective effect is afforded with 1.5 molar solution. The concentrations above this value are not more efficient.

In Fig. 2, the relative heights of the first leaves for 4, 8 and 12 krad are plotted against the osmotic potential

of the solutions. For each dose, an increase of the osmotic potential from  $-2.5$  to  $-7.5$  joules  $\text{cm}^{-3}$  (ref. 5) brings a rapid augmentation in length of the leaves. The X-ray sensitivity of seeds particularly decreases only in a relative narrow range of concentrations.

The experimental evidence suggests that the protective effects of different salt solutions are related to their osmotic properties since they are not specific.

Two separate mechanisms involving osmotic effects can be considered as operative to explain this increase of resistance to X-rays. The consequences of the decreasing difference in the water potential between the more and more concentrated solutions and the cells of the seeds can to some extent make the latter less susceptible to irradiation.

However, our results involving reduction of the pre-irradiation humidity of the seeds by osmotic pretreatment differ from those obtained after soaking the seeds for different periods of time, or conditioning them at various constant humidity systems. A striking diminution of the growth above and below an optimum humidity was observed<sup>1,2</sup>. As this is not the case with our results, it

Fig. 1. Effects of the osmotic potential of calcium chloride solutions on the water content of barley seeds

Fig. 2. Influence of osmotic potential of calcium chloride soaking solutions on the first leaf growth from barley seeds treated by different X-ray doses (S.D. is indicated)

is possible that induced modification of the water content of the seeds by various osmotic concentrations is not a determining factor.

A decrease in the amounts of ninhydrin positive substances leached out of the barley during soaking<sup>2</sup> and an activation of the hydrolysis of polysaccharides (anatonosis) result from increasing osmotic concentration of the external medium. Thus in the cells of the embryo an increased concentration of natural chemical protectors may be expected from a reduced loss of protides and increased content in sugars. This hypothesis explains the fact that beyond a certain osmotic potential the protection does not increase any further, since, as shown by Kamra *et al.*<sup>3</sup>, a plateau is reached in the loss of ninhydrin-positive substances at approximately the level of osmotic concentration which is optimal for radioprotection.

### Use of Gamma-radiation for Quarantine Control of Imported Edible Beans

APPROXIMATELY 4,000 tons of edible beans, mainly *Phaseolus vulgaris* varieties, are imported into Australia annually. Under the quarantine regulations<sup>1</sup>, the majority of these beans are treated on entry to destroy their viability, thereby preventing the introduction and transmission of various plant diseases. Methyl bromide is commonly used for this purpose. It was decided to investigate the possibility of using  $\gamma$ -radiation as an alternative method of treatment, as it is well known that low doses of  $\gamma$ -radiation inhibit seedling growth<sup>2-4</sup>. The radiation dose required to destroy viability in several different varieties of imported beans was therefore determined, as well as the effects of radiation on various chemical constituents of one type of bean, the baby lima.

Permission was obtained from the Commonwealth Department of Health to import unfumigated beans of the following varieties: sallugia, ohtenashi, borlotti, baby lima, red kidney, Michigan pea, and black-eye. Large quantities of navy beans and smaller quantities of butter beans are also imported, but for these tests locally grown seeds were used. Packets of approximately 500 g of beans, enclosed in double polythene bags, were irradiated, using either spent fuel elements from the reactor *Hifor* or cobalt-60. Dosimetry was by the ferrous sulphate method<sup>5</sup>, three dosimeters being included in each packet.

After the beans were treated with a mould inhibitor ('Coversan'), laboratory germination tests were carried out either on sand or on paper towelling which had been sterilized by a radiation dose of 2.5 Mrads. The seeds were incubated for 9-20 days at 25° C. Although 9 days is the recommended time<sup>6</sup> for germination tests on *Phaseolus vulgaris* seeds, this period was found to be too short for an accurate assessment of germination of irradiated seeds. After incubation for 9 days, seedlings grown from irradiated seeds may show all the structures

considered essential for normal growth, although the seedling height is greatly reduced, and the seed coat may still be attached. Further incubation results in very little difference in the appearance of these seedlings: the seedling height remains unchanged and, even if the seed coat comes away, the cotyledons remain closed. If the mean seedling height of the irradiated beans, after 14 days testing, failed to exceed 10 per cent of that of the controls, it seemed reasonable to assume that these beans would never reach maturity.

Based on these considerations, Table 1 sets out the radiation dose needed to meet the quarantine requirements for various edible beans, as estimated by laboratory germination tests conducted over 14 days. At these doses the maximum seedling height would be 3 cm; there would be no protrusion of possibly infected leaves, and no possibility of growth to maturity. A limited amount of evidence obtained in preliminary tests using French bean seeds indicated that irradiated seeds may show a higher percentage of germination under laboratory conditions than under field conditions. Hence, it may be possible to reduce the radiation dose required for quarantine control.

Table 1. ESTIMATED RADIATION DOSE REQUIRED FOR QUARANTINE CONTROL (Calculated from laboratory germination tests)

Type	Dose (rads)
Red kidney	<40,000
Michigan pea	40,000
Navy	>40,000
Sallugia	50,000
Ohtenashi	50,000
Borlotti	55,000
Baby lima	55,000
Butter	75,000
Black-eye	80,000

The average radiation dose required to inhibit laboratory germination is about 50,000 rads. It was expected that the chemical changes in beans given this dose would not be great, and therefore the effects of a dose of 1 Mrad on the nutrients of baby lima beans were examined. Only when there were considerable differences between the values for control and irradiated beans was the effect of the 50,000-rad dose-level investigated.

Before analysis, baby lima beans were ground to pass through an 85-mesh sieve. Moisture (vacuum oven method), ether extract (indirect method), and ash (direct method) were estimated as described by the Association of Official Agricultural Chemists<sup>7</sup>. Total nitrogen was determined using the micro-diffusion technique<sup>8</sup>. Thiamin (thiochrome method) and riboflavin (fluorimetric method) were examined by methods outlined by the Association of Vitamin Chemists<sup>9</sup>. Sulphydryl and disulphide groups were determined directly on the flour by an automatic amperometric titration method using silver nitrate<sup>10</sup>, and the radiometer titrator recording equipment. All determinations were carried out at least in duplicate.

The results are set out in Table 2. Apart from the sulphur-containing constituents, little change was apparent in the constituents after irradiation. Riboflavin content appeared to increase. However, in view of the sensitivity of riboflavin to  $\gamma$ -irradiation<sup>11</sup>, it seems possible that the higher concentration of riboflavin in the irradiated seeds was due to fluorescent artefacts which were not being extracted during the procedure. An apparent increase in

Table 2. EFFECT OF  $\gamma$ -RADIATION ON CONSTITUENTS OF BABY LIMA BEANS

Constituent	0	Dose (Mrads) 0.05	1
Moisture: g/100 g wet wt.	10.69		10.20
Ether extract: g/100 g wet wt.	1.13		1.27
Total nitrogen: g/100 g wet wt.	2.97		2.96
Ash: g/100 g wet wt.	3.80		3.80
Thiamin: $\mu$ g/100 g wet wt.	860	970	760
Riboflavin: mg/100 g wet wt.	0.083	0.104	0.093
Sulphydryl groups: $\mu$ mole/g	6.53	4.65	3.73
Disulphide group: $\mu$ mole/mg N	0.22	9.16	0.13
	11.50	2.22	2.22
	0.39	0.23	0.07

riboflavin has been noted in other products when treated by irradiation or by other processing methods<sup>12</sup>.

Sulphydryl and disulphide groups were determined, not so much because of their nutritional importance, but because it is generally considered that these groups are particularly sensitive to radiation<sup>13</sup>. Although the majority of experiments elsewhere have involved only solutions containing low concentrations of these groups, similar results were obtained in these experiments using bean flour. There was a considerable decrease in both groups following irradiation.

I thank Miss L. D. Hook and Messrs. A. J. Morris and J. Taylor for their assistance, and Miss A. Myers, New South Wales Department of Agriculture, for advice.

## BIOLOGY

### Far Southern Animals and Plants

IN recent years the southern limits of known natural occurrence of animals have been pushed farther south, and during the 1964-65 Antarctic season several new southernmost records were established. Records of the most southern plant collections made this season are also included here.

In 1959, Tyndale-Biscoe<sup>1</sup> found one species of mite (Acarina) and two species of springtails (Insecta), with lichens and moss, between the Hood and Beardmore Glaciers, 83° 45' and 83° 55' S. The mite is *Nanorchestes antarcticus* Strandtmann, 1963 (Prostigmata: Pachygnathidae) and the springtails *Bischoia subpolaris* Salmon, 1962 (Collembola: Hypogastruridae), *Anurophorus subpolaris* Salmon, 1962 (Collembola: Isotomidae).

Recently, Wise<sup>2</sup> recorded *N. antarcticus* and *A. subpolaris* from near the lower Shackleton Glacier at 84° 35' S.

The preliminary records listed here are presented before complete identification of the groups concerned, as some identifications must await opportunity for detailed systematic work. Records presented here are listed in latitudinal order from south to north. They represent, in most cases, the most southern collections made, of the various elements of the biota, during the 1964-65 season. These are probably also, in each case except for the mosses, the southernmost known occurrences for these groups.

Lichens: Ridge west side unnamed glacier west of Wisconsin Range, Horlick Mts. area; 86° 09' S., 131° 14' W.; alt. 1980 m; 15.I.1965; Wise (site HM18).

Mite, *Nanorchestes antarcticus* Str.: Pt. Durham area, east side mouth of Robert Scott Glacier; 85° 32' S., 153° W.; alt. 975 m; 13.I.1965; Wise (site RS3).

Rotifers; Algae (macroscopic): Swithinbank Moraine, west side Shackleton Glacier; 85° 09' S.; 176° 50' W.;

alt. 1,600 m; 1.XII.1964; Gressitt (algae, rotifers) (site S25), Wise (algae) (site S1).

Algae (microscopic); Bacteria: South side McGregor Glacier, near Shackleton Glacier; 85° 09' S., 174° 57' W.; alt. 1,737 m; 17.XII.1964; Wise (soil) (site S8); cultured by J. Shoup.

Springtails, *Anurophorus subpolaris* Salm., *Tullbergia* sp. (Onychiuridae); Mites, *N. antarcticus* Str., ? *Stereotylus mollis* Wom. and Str., ? *Proteronides* sp.: east side Shackleton Glacier; 84° 47' S., 176° W.; alt. 762 m; 13.XII.1964; Wise (site S16).

Moss: Garden spur, east side Massam Glacier, east of Shackleton Glacier; 84° 35' S., 174° 52' W.; alt. 700-762 m; 13.XII.1964; Wise (site S20). Point east side Barrett Glacier, east of Shackleton Glacier; 84° 35' S., 173° 35' W.; alt. 457 m; 13-14.XII.1964; Wise and J. Shoup (site S21). (E. V. McGregor, N.Z. Antarctic Research Programme, collected moss at both these sites in 1963-64, and apparently also at Cape Smith, 84° 42' S., 170° W.)

The map (Fig. 1) indicates the areas mentioned in the foregoing list and also inland Antarctic areas which have been found, by Bishop Museum personnel, to be negative for fauna<sup>3</sup>. The latter include the Queen Maud Mts. above 1,600 m, the Ellsworth Mts. (77°-80° 30' S.), the Whitmore Mts. (82° 20'-82° 45' S.), Pagano Nunatak and Hart Hills (88° 40' S.), and the Horlick Mts. (84° 35'-86° 20' S.). Lichens have been found in some of these ranges. The most southerly area of bare ground is about the Robert Scott Glacier. This and other large areas between Beardmore-Shackleton-Robert Scott Glaciers still remain to be investigated. Much of the bare ground lies at relatively low altitudes even though these areas appear to be far inland. Actually, the landward edge of the Ross Ice Shelf must be considered coastal, the sea and shores being covered with ice a few hundred metres thick.

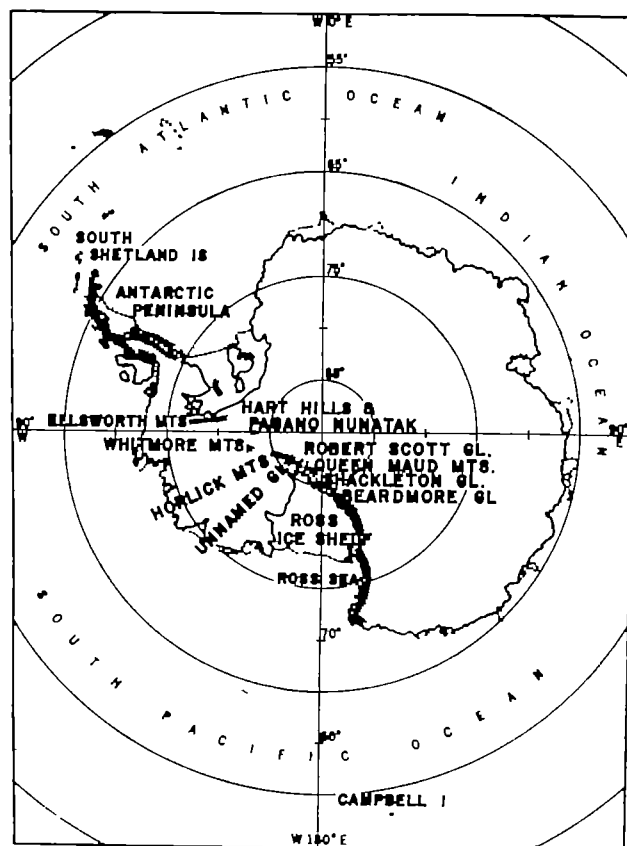

Fig. 1. Map of Antarctica, showing areas positive and negative for biota in inner Antarctica, as mentioned in text. Heavy hatched lines are principal mountain ranges pertinent to the discussion.

Biotic environments occur mainly on northward facing slopes with snow patches, on flats below permanent snow-ice slopes, on cliffs with snow patches, on ice-cored moraines, or on flats above glacier levels where snow-clouds, blown snow or clay beneath the substrate provide a source of moisture. The obvious key factor to a faunal environment is the daily rise of soil temperatures above freezing point together with the presence of available moisture. In the far south, and at higher altitudes farther north, snow and ice recede, in the summer, through sublimation. Even though soil temperatures may rise above 0° C the soil may still be quite dry. It is only where there is local melting of snow or ice that fauna can survive.

The southern records noted here are of interest not only for the actual geographical positions but also for the ecological factors involved, particularly length of continuous light and dark periods, and length of periods when soil temperatures rise above freezing point, as well as the distributional factors involved in placing biota in such areas. So far as is known at present there is no indication, in the fauna, of species in the central (southern) area of Antarctica linking species in the peripheral (northern) areas of the Ross Sea sector with those of the Antarctic Peninsula, but the recently discovered *Tullbergia* species has yet to be examined particularly in regard to its relationship with Campbell I.<sup>4</sup> and South Shetland Is. species.

These are partial results of work on the U.S. Antarctic Research Programme, supported by grant GA-131 to Bishop Museum from the U.S. National Science Foundation.

### Differences in Regulation in the Silk Glands of the Spider

It has been found that the production of fibroin from the ampullate glands of the spider, *Aranus sericatus*, can be stimulated both by cholinergic agents and by emptying the gland<sup>1</sup>. However, as will be shown here, the cylindrical glands do not have a cholinergic regulatory mechanism.

The basic work on the structure and function of the silk glands of *Aranus diadematus* was carried out at the end of the nineteenth century<sup>2,3</sup>, by workers who carried out careful investigations based on gross dissection, observation of which spinneret was used, the presence or absence of certain types in certain families or, in the case of the egg-cocoon glands, presence only in the female. It was postulated that the ampullate glands produced the fibroin for the scaffolding of the web, the aggregate glands the viscid thread, and the cylindrical glands the egg-cocoon fibroin. By serial sectioning the spider after it had performed a certain action which involved the use of silk and checking the state of filling of the glands, it was possible to determine with certainty which glands are involved in producing fibroins for a given purpose<sup>4</sup>. It has been demonstrated by these means that the scaffolding of the web and the safety thread come from the ampullate glands and that the aggregate glands are involved in the formation of the catching spiral. If thread is drawn from

Fig. 1. Sections showing the cylindrical glands (C) before (a) and after (b) construction of the egg-cocoon. Some aggregate glands (A) are also visible. Note the full glands as normally found compared with the empty lumen after the construction of the cocoon (haematoxylin and eosin,  $\times c. 200$ ).

the spider by winding it on to a rod which is turned by a small motor, it is the ampullate glands alone which are emptied<sup>4</sup>. The cylindrical glands are normally full of protein (Fig. 1a), but after the completion of the egg-cocoon they are found to be empty (Fig. 1b). Our observations on *Aranus diadematus* and *Aranus sericatus* have revealed no differences in any of the respective silk glands of these two species.

It has been shown by two methods that the rate of incorporation of amino-acids into the ampullate gland is stimulated by cholinergic agents both *in vivo* and *in vitro*<sup>1,5</sup>. The amount of incorporation of alanine labelled with carbon-14 into the fibroin was measured by determining the radioactivity of the fibroin pulled from the spider. Also the course of the incorporation of <sup>14</sup>C-alanine into the ampullate glands was followed by means of autoradiographs. Both methods showed that physostigmine and carbachol both increased the rate of incorporation to approximately double the normal rate. The ampullate glands can also be stimulated by emptying out the fibroin. This stimulation, unlike the cholinergic mechanism, is not blocked by atropine. Thus there is evidence for the existence of two, more or less, independent mechanisms to regulate the protein production in the ampullate gland. The cylindrical gland is different from all the other silk glands of the spider in that it is not in daily use. Egg cocoons are normally made only once or twice in the life of a spider<sup>4</sup>. Autoradiographs show no stimulation of the activity of the cylindrical gland after the administration of physostigmine. This is shown in Fig. 2, where it can be seen that there has been no incorporation into the cylindrical gland although there is considerable radioactivity in the aggregate gland. It can also be seen

from the photograph that the epithelium of the cylindrical gland is narrow and contains very little DNA or RNA, as would be expected in an inactive gland.

Thus it is found that the cholinergic mechanism is present only in those glands which are used daily and is absent in the cocoon-producing glands which are used infrequently.

Fig. 2. Autoradiographs of aggregate (a) and cylindrical (b) glands. Both photographs are from the same section the glands are 0.006 mm apart. The spider was fixed 8 h after oral administration of  $^{14}\text{C}$ -alanine and 1 mg/kg physostigmine. The black dots, formed on the photographic emulsion covering the slide, show the location of the labelled alanine. Considerable activity is found in the lumen of the aggregate gland (a) (two dots are indicated by arrows) showing the presence of freshly synthesized silk whereas the cylindrical glands (b) show no activity (azure B,  $\times$  c. 500).

## ENTOMOLOGY

### Finding Metarchons for Pest Control

SALMOTIVE control of pest insects by behaviour-controlling scents or other metarchons<sup>1</sup> promises to become a preferred method, but if, as seems probable, the scents to which insects respond are in most cases blends of several distinct chemical substances, the problem of isolating and identifying the active materials becomes very difficult<sup>2</sup>. This control method is based on the assumption that by sufficiently permeating the environment with a particular scent, such as a sex attractant, either the males will be unable to perceive the small increment released by the female or, what is effectively the same thing, their receptors will become fatigued and temporarily cease to register any signal.

The question now arises whether, in order to block the response, it is necessary to disseminate all the components of a complex scent, or whether it is sufficient to raise the background concentration of one or possibly a few constituents of the blend to which the creature normally reacts.

A large wind tunnel, 2 x 2 x 10 ft. and containing some hundreds of fruit-flies (*Drosophila melanogaster*), was used as an olfactometer<sup>3</sup>. The up-wind end of the main observation chamber was closed by a wire screen behind which could be concealed an attractive bait of fermenting bananas which was shown by vapour-phase chromatography to consist of at least ten components. The fruit-flies had no difficulty in locating and congregating on the part of the screen through which the scent was emerging. Up-stream from the screen and the attractive bait, the tunnel narrowed to a 6-in. inlet pipe. A porous polyurethane sponge 2 in. thick could be fitted into this inlet and moistened with various liquids so as to permeate the incoming air before it passed over the bait and through the screen.

When the sponge was treated with 30-50 ml. of ethyl alcohol, the fruit-flies continued to locate the attractive area without difficulty, but when sponges similarly treated with ethyl acetate or amyl acetate were used, the insects' ability to find the lure disappeared entirely. Other substances which were effective in hiding the bait when added to the air stream were acetone and glacial acetic acid (the vapour of which also produced a considerable mortality); while propyl alcohol and 2,3-butanedione ('Biacetyl'), like ethanol, had little if any ability to hide the scent. Geraniol, which has a powerful smell and is strongly attractive to the Japanese beetle but not to *D. melanogaster*, was likewise completely effective in preventing the fruit-flies from congregating in the scent stream from the fermenting fruit.

While these experiments were made with a food odour, there is no reason to suppose that a sex-attractant scent or oviposition lure would not act similarly. If so, the search for practically useful metarchons should be greatly simplified. In place of the tedious process of isolation, identification and synthesis of the components of the natural scent, or the too-often unrewarding mass screening of thousands of organic compounds for signs of attractiveness, all that is required is a direct test of various materials for their ability to interfere with the perception of a specific scent by a particular insect. This could be done, for example, by placing male insects in a wind tunnel,

concealing females behind the inlet screen, and adding the test substances to the air intake. Not only would this provide a direct route to metarhcon formulation, but it would throw considerable light on the olfactory process itself.

### Damage to Polythene by Aquatic Moths

RECORDS of damage to polythene by insects are now fairly frequent. The larva of the common household pest *Hofmannophila pseudospretella* Stainton (the Brown House or False Clothes moth) is known to eat its way through many man-made products, including polythene, polystyrene, and nylon.

Recently the larvae of an aquatic lepidopteran species were found damaging the polythene linings of ponds (1,000 gauge, approx. 0.25 mm thick). The damage to the inner lining of the pond was caused by the larvae of the moth eating holes through the polythene to the rough paper outer-lining. The larvae then attached themselves to this outer-lining paper before pupating. After the moths emerged the pupal cases were soon washed away, leaving holes of 1–3 mm diameter. This damage occurred both in a greenhouse where the pond was a wood-framed structure with a paper underlay and a polythene lining, and out-of-doors where soil was underneath the polythene. All the holes were at or just above water-level.

It is possible that the very smooth polythene failed to provide a suitable surface on which the larvae could anchor themselves before pupation and that they therefore chewed through to a rougher surface. Perhaps if the polythene surface was rougher the larvae would attach themselves without burrowing through it. The damage was first noticed in 1964 although the polythene had been in use for 7–8 years.

Specific determination of the moths was not possible in the sample examined, as all the pupal cases were empty. However, it is certain that the moths concerned were a species of *Hydrocampinae* (*Pyralidae*) and almost certain that the species was *Nymphula nymphaea* Linnaeus, the Brown China-Mark moth.

### MICROBIOLOGY

#### Variation in the Chemical Composition of the Cell Walls of *Bacillus subtilis* during Growth in Different Media

DURING recent years the chemical composition of the cell wall has been used as an aid in the classification of micro-organisms<sup>1</sup>. Although differences in the composition of the cell wall have been demonstrated during growth of organisms with: (a) variable morphological forms<sup>2</sup>; (b) complex auxotrophic requirements<sup>3</sup>; (c) addition of D-amino-acids<sup>4</sup>, many investigations have not considered the variations which occur in the amino-acid and amino-sugar content of more stable strains of bacteria during the growth cycle and in response to different growth media. The results presented here demonstrate that the amino-acid and amino-sugar content of the cell wall of *Bacillus subtilis* varies not only with growth but is also

significantly influenced by the composition of the growth medium. Furthermore, galactosamine, one of the major components of the cell wall of the highly transformable strain *B. subtilis* 168 I-O<sup>+</sup>, is consistently decreased when this strain is grown under conditions which do not permit the development of the capacity to bind deoxyribonucleic acid (competence). A marked decrease in galactosamine is also observed in three poorly transformable strains of *B. subtilis*.

*B. subtilis* 168 I-O<sup>+</sup> was grown for various intervals at 37° C with vigorous aeration in 800-c.c. cultures contained in 2-l. flasks. Three media were used: (A) the standard growth medium containing 0.5 per cent glucose, 0.005 M MgSO<sub>4</sub>, 50 µg/ml. L-tryptophan, and 0.02 per cent casein hydrolysate<sup>5</sup>; (B) the previous medium supplemented with 0.4 per cent casein hydrolysate; (C) 'Pen Assay' broth (Difco). *B. subtilis* 168 does not sporulate in these media under the experimental conditions used. The organisms were collected by centrifugation, washed and disrupted by mechanical disintegration<sup>6</sup>. Samples of cell walls were dried over phosphorus pentoxide, hydrolysed at 105° ± 1° C for 11 h in 4 N hydrochloric acid, and evaporated *in vacuo* to remove the hydrochloric acid. The amino-acid and amino-sugar content was determined on the Beckman Spinco amino-acid analyser<sup>7</sup>.

Previous experiments have shown that logarithmic growth in medium A occurs 1.5–5 h after incubation<sup>8,9</sup>. The culture then remains in a stationary period for 3 h before a marked decrease in the number of viable organisms occurs. As shown in Table 1 the major amino-acids and amino-sugars in the cell wall of *B. subtilis* are alanine, glutamic acid, diaminopimelic acid, muramic acid, glucosamine, and galactosamine. During the logarithmic and early stationary phases of growth (1.5–8 h) the amounts of glutamic acid, diaminopimelic acid, and glucosamine do not vary beyond the limit of the accuracy of this method (± 5 per cent on repeated analyses of the major components in the same sample of cell walls). On the other hand, the content of alanine within the cell wall increased during incubation. A consistent decrease in muramic acid was observed after 5 h of growth. The highest concentration of galactosamine occurred after 5 h of incubation which coincided with the time that the population developed maximal competence. Since the galactosamine is confined to the teichoic acid fraction of the cell walls<sup>10</sup>, this two-fold increase in galactosamine might significantly alter the structure of the cell wall. After 24 h of incubation there was an increase in all the major components except galactosamine. The small differences in the minor components (aspartic acid to arginine, Table 1) are not significant.

Previous investigations have demonstrated that growth in nutrient media such as media B and C inhibit the development of competence<sup>8</sup>. As shown in Table 2, there is an increase in alanine and a decrease in galactosamine under these conditions of growth. This decrease in galactosamine was observed after both 3 and 5 h of incubation in 'Pen Assay' broth.

Two additional poorly transformable strains of *B. subtilis* were examined. *B. subtilis* 23 is an excellent donor strain in transformation experiments, but a very poor recipient. *B. subtilis* H is essentially not transformable. As shown in Table 3, the most outstanding difference was in the galactosamine content of the cell wall. At present it is not known whether galactosamine is an integral part of the teichoic acid polymer or is in another polymer which is fortuitously isolated with the teichoic acid fraction during purification. Nevertheless, it is clear that galactosamine varies during the growth cycle and is decreased when the transformable strain is grown in more complex media. In addition, the concentration of galactosamine is markedly decreased in the two poorly transformable strains used in this work and in a poorly transformable mutant of *B. subtilis* 168 (ref. 6).

# NEW RANGE OF CAMBRIDGE AC-DC RESISTANCE BOXES **QUICK DELIVERY**

A new Cambridge range of decade resistance boxes made to designs based on long experience in the manufacture of precision electrical instruments for research and industry.

**FEATURES:**

- Accuracy of adjustment  $\pm 0.06\%$  over greater part of range
- Long term stability
- Minimum self-inductance and distributed capacitance
- Use of manganin and similar materials with low temperature coefficients and small thermal e.m.f.s. with copper
- Switches incorporating copper brushes and silver-faced contacts
- Metal case of modern styling provides electrical shielding and carries screen terminal
- 3, 4 and 5 dial resistance boxes available—total resistance ranging from 111.1 ohms to 111 110 ohms

Write for NEW List SA165N. For future publications ask for Mailing Form N/7/65

These results demonstrate that changes occur in the structural mucopolysaccharide of the cell wall during growth and in various growth media. Although such differences are not as marked as those observed in organisms with

pleomorphic growth patterns, they are of sufficient magnitude to warrant the use of a variety of cultural conditions in studies of the structure of the cell wall of micro-organisms.

### Prevention of Competitive Suppression in Microbial Plating Experiments

An assumption inherent in back-mutation experiments is that at the cell concentrations used 'background' prototrophs in a substantially auxotrophic population will be expressed quantitatively in the form of colonies or turbid culture when the mixed population is incubated on or in the basal medium. This is not always valid<sup>1,2</sup>. Fewer prototrophs may appear than expected when high cell concentrations are used, because the growth of prototrophs is suppressed by the presence of sufficiently large numbers of auxotrophs. This is referred to as 'competitive' suppression<sup>3</sup>. On diluting a suspension of auxotrophic cells to different degrees in basal medium the frequency of back-mutant colonies which arises may increase as the dilution rate increases and the suppression decreases.

Competitive suppression occurs as a result of the removal of carbohydrate from the selective medium by the non-growing (auxotrophic) population so that it is not available for the growth of the mutant or back-mutant species being selected for<sup>1,2</sup>. This starvation can be prevented if an energy source is used which the bulk of the population cannot utilize but which the mutant being selected can. Such a situation is achieved (a) if the microbial strain can adapt to use some particular energy source, for example, a *lac*<sup>+</sup> (*tyr*<sup>+</sup>) strain of *Escherichia coli* on lactose medium, and (b) if the mutation being studied is a back-mutation from an amino-acid requirement to a non-requirement, that is, prototrophy. If the *lac*<sup>+</sup> strain and lactose are chosen as the strain and substrate respectively the bacteria should be grown under conditions which prevent adaptation to lactose utilization, and starved of the required amino-acid to exhaust the metabolic pool. Back-mutants can then be selected on medium containing lactose as the energy source. Since the latter would be able to synthesize the required amino-acid they could make  $\beta$ -galactosidase and hence could utilize lactose for growth. The auxotrophs, on the other hand, would be unable to make the enzyme and thus could not utilize the sugar.

Should it be desirable to allow several replications of the microbial population on or in the selective medium, sufficient glucose should be added to the lactose medium with the amino-acid supplement to leave an excess of glucose after the complete utilization of the amino-acid to ensure that adaptation to lactose is repressed.

Table 1 presents the data of two experiments to illustrate the effectiveness of this experimental design in eliminating competitive suppression. Overnight cultures of *trp*<sup>-</sup> (*wp*, Witkin<sup>4</sup>) bacteria grown to exhaustion of glucose were incubated in a glucose basal medium for 3 h to exhaust their amino-acid pool of tryptophan. Aliquots of the washed bacteria were spread on glucose and lactose

Table 1. INFLUENCE OF DURATION OF GROWTH ON THE CHEMICAL COMPOSITION OF THE CELL WALLS OF *Bacillus subtilis*

*B. subtilis* 168 I-C<sup>+</sup> was grown for various intervals in medium A. Maximal competence occurs after 5 h of growth. The frequency of transformation usually varies from 0.4 to 0.8 per cent at this time. An additional 3-8-fold increase in transformation can be obtained if the cells are centrifuged and resuspended in the transformation medium described previously<sup>4</sup>.

\*Minute colonies.

basal media and the numbers of prototrophs scored. In one experiment different numbers of bacteria were spread on lactose medium to look for a dilution effect.

In experiment 1 (Table 1) significantly more *tryp*<sup>+</sup> colonies appeared on the lactose than on the glucose medium. Moreover, the *tryp*<sup>+</sup> colonies in the latter were minute in size. When the number of *tryp*<sup>-</sup> bacteria was increased by 30 per cent in experiment 2, the discrepancy between the numbers of *tryp*<sup>+</sup> colonies observed became considerably greater—presumably more were suppressed. Also the variance of the mean number of prototrophs was much higher on the glucose medium group. This is a common feature of the suppression effect when the number of suppressing bacteria reaches a threshold value<sup>2</sup>.

On the lactose plates a strict proportionality between the number of *tryp*<sup>-</sup> bacteria plated and *tryp*<sup>+</sup> colonies observed was found (exp. 2, Table 1), that is, there was no 'dilution effect' and hence no competitive suppression.

Besides avoiding minor or major errors in plating experiments the use of this selection technique, by preventing competitive suppression, has made it safe to use high densities of bacteria in selection experiments. It should be of general applicability in a modified form to other microbial species.

It has the further particular advantage that in any experiment requiring bacteria to remain on the selective medium for a relatively long period the use of non-adapted cells and lactose as the energy source almost entirely prevents cell death<sup>3</sup> and the complication this can introduce in assessing viabilities.

## VIROLOGY

### Replication Cycle of an Insect Granulosis Virus

WHEN a lepidopterous larva such as a cutworm (Noctuidae) in a late stage of infection with a granulosis virus is shaken up in distilled water, as much as 10 ml. of a

Fig. 1. Section through two granules, side by side in the same cells; note the apparent extrusion and elongation of the virus rod, the outer membrane now encloses only half the rod (arrows), note also an apparent membrane surrounding the granules. ( $\times 82,500$ )

Fig. 2. Low power electron micrograph of a section through a mass of branching virus threads inside the cell. ( $\times 40,000$ )

fluid of the consistency of thin cream is obtained. This consistency is due to the immense numbers of protein crystals, the granules, each containing a short virus rod, which are liberated from the insect's tissues. Centrifugation of this fluid for 30 min at 5,000 r.p.m. causes the granules to form a sediment and gives a clear supernatant with a greenish opalescence. When this opalescent fluid is examined with the electron microscope it is found to contain large numbers of long virus-like threads branched in an intricate manner.

This communication is concerned with the origin of these threads and the part they are thought to play in the replication cycle of the virus.

In a previous communication<sup>1</sup> the suggestion was made that the short thick virus rod emerged from its occluding crystal, lengthened in the process and commenced to branch. Since these observations were all made on purified preparations of the virus threads and their concomitant granules, the criticism could be made that some of these phenomena were artefacts arising from the negative staining with phosphotungstic acid. The peculiar

Fig. 3. Similar to Fig. 2 but at higher magnification; the branching of the threads is clearly visible. ( $\times 100,000$ )

Fig. 4. A long virus thread negatively stained with phosphotungstic acid, note the internal helix (arrow). ( $\times 100,000$ )

branching of the virus might also be attributed to adsorption of the various lengths.

Further investigations have now been made, but this time on thin sections of infected tissue fixed in osmium tetroxide and stained with uranyl acetate and lead citrate. The changes described here all occurred inside the cell itself. Based on these results, an explanation is offered of the origin of the long virus threads and of their role in the replication of the virus. The cycle proposed is a tentative one, but it appears to fit most of the observed phenomena.

As previously suggested<sup>1</sup>, the initial step in the replication cycle seems to be the extrusion of the short thick virus rod from its occluding protein crystal, the granule. To this end there appears to be a cap on one end of the crystal which lifts up to allow exit of the virus particle. In addition to being occluded in the crystal, the virus is also completely enclosed in an outer membrane.

Numerous examples have now been observed of this extrusion process occurring inside the cell. As the rod emerges from the crystal it increases in length and decreases in diameter; the outer membrane in which the particle was originally completely enveloped is sometimes pushed out with it. In Fig. 1 are sections of two crystals side by side in the same cell; in one is the short thick virus rod with its enveloping membrane. In the other the virus rod is in process of emergence, and it is noteworthy that the outer membrane, pushed out by the emerging rod, now envelops only half its length. Empty membranes and the U-shaped empty granules can be found loose in the cell.

It is of interest to speculate on the nature of the stimulus which causes the virus rod to emerge from the crystal.

Perhaps the most interesting phenomenon in this replication process is the apparently unlimited and uncontrolled branching of the long virus threads, a phenomenon that, so far as we know, is unique among viruses. That the branching is a genuine phenomenon and that it occurs inside the cell cytoplasm are shown in Figs. 2 and 3. The reason for the branching is at present obscure, unless it is a means of increasing the DNA which must be inside the long thread.

High-resolution electron micrographs of the virus threads suggest that they are composite with an inner helical core. Fig. 4 shows one of these threads negatively stained with phosphotungstic acid. The stain has apparently entered, possibly by a small break in the outer coat, and delineated the internal helix.

Presumably the next step in the replication process is the break-up of the long thin virus threads into the short rods. Lying free in the cell cytoplasm there occur single short rods, some with, and some without, their outer membrane. The last stage in the replication process seems to be the deposition on the finished virus rod of the protein to form the occluding granule as originally suggested by Hughes<sup>2</sup>.

We thank Dr. Hilton Mollenhauer for assistance with the electron microscopy.

## GENETICS

## Inheritance of a Correlated Day-length Response in Spring Wheat

In the course of genetic and physiological studies of developmental processes leading to flowering in spring wheats a major gene conditioning a positive response to vernalization was detected in the variety 'Insignia 49' (ref. 1). Further investigations have now led to the recognition of a second gene governing the photoperiodic response of the Canadian variety 'Selkirk'.

The work was based on two varieties—'Triple Dirk', a back-cross derivative of the Australian variety 'Dirk 48', and 'Selkirk'. I have found (in unpublished work) that 'Triple Dirk' is not responsive to vernalization, and although no tests have yet been undertaken, it seems likely that 'Selkirk' would be unresponsive as are so many Canadian varieties.

When grown at Wagga Wagga (latitude 35° 5' S) during the long days of summer (day-length 13.5–14.5 h) 'Triple Dirk' and 'Selkirk' are comparable in maturity. Sown on December 26, 1963, the two varieties came into ear in 52 days. When sown in the greenhouse in the autumn and grown throughout the cooler short days of winter (day-length 10.5–11.5 h), flowering of both is delayed, with 'Selkirk' much more sensitive than 'Triple Dirk'. Sown on April 15, 1964, the number of days to ear emergence for 'Triple Dirk' and 'Selkirk' was 94 and 132 respectively.

An *F*<sub>1</sub> and *F*<sub>2</sub> of the cross 'Selkirk' × 'Triple Dirk' and the *F*<sub>1</sub> of the back-cross ('Selkirk' × 'Triple Dirk') × 'Selkirk' sown at the same time showed: (a) almost complete dominance of earliness; (b) an *F*<sub>2</sub> ratio of 34 early : 7 late, (c) an *F*<sub>1</sub> back-cross ratio of 23 early : 22 late. The

two segregations fit 3:1 and 1:1 ratios with *P* values > 0.2 and > 0.8 respectively. The distribution of the segregating populations is set out in Figs. 1 and 2.

It is of interest to report a complete association of maturity with the number of leaves on the primary tillers at ear emergence and also with the number of spikelets on the same primary tillers. The relevant data for the parents, the *F*<sub>1</sub> and the two segregating populations are set out in Table 1.

Table 1. CORRELATED BEHAVIOUR OF TIME TO EAR EMERGENCE AND NUMBER OF LEAVES AND SPIKELETS ON PRIMARY TILLERS

	Range in number of days to ear emergence	Range in number of leaves on primary tillers	Range in number of spikelets on ears of primary tillers
'Selkirk'	130–134	9–10	25–27
'Triple Dirk'	92–97	7–8	16–17
'Selkirk' × 'Triple Dirk', <i>F</i> <sub>1</sub>	93–96	7–8	16–18
'Selkirk' × 'Triple Dirk', <i>F</i> <sub>2</sub> early segregates	85–120	7–8	17–23
'Selkirk' × 'Triple Dirk', <i>F</i> <sub>2</sub> late segregates	131–138	9–10	23–27
('Selkirk' × 'Triple Dirk') × 'Selkirk', <i>F</i> <sub>1</sub> early segregates	93–112	7–8	17–23
('Selkirk' × 'Triple Dirk') × 'Selkirk', <i>F</i> <sub>1</sub> late segregates	125–133	9–10	23–27

The early and late classes of both segregating populations were separated by gaps of 18 days for the *F*<sub>2</sub> and 11 days for the *F*<sub>1</sub> back-cross. There was no inter-class overlap with respect to the leaf number and spikelet number classes.

As far as the writer is aware this is the first occasion in which a clearly defined monohybrid segregation governing a correlated response to short days has been reported in *Triticum*. This finding is significant in both its basic and applied aspects. The presence of a single gene pair conditioning the behaviour of wheat varieties to short days would suggest the operation of a simple physiological process leading to ear initiation. Similarly, the simple mode of inheritance makes possible a much greater degree of control by the plant breeder in fashioning varieties adapted to specific day-length environments. Maturity control may now be achieved through the use of specific major genes operative through either a vernalization or a day-length control mechanism.

Just as the spikelet number on the primary ear of a given variety may vary with the day-length to which the plants are exposed prior to ear initiation, so too is it under genetic control in a segregating population such as that described herein. Furthermore, the association of spikelet numbers with maturity differences has many implications in wheat improvement programmes as well as in agronomic practice.

Unpublished investigations by me suggest that additional genes may be involved in other crosses between sensitive and less sensitive varieties.

## ABO Blood-groups in Leukaemia

It has been shown that the blood group A is of some importance in the multifactorial genetic system of sarcooidosis<sup>1,2</sup>. It may be postulated that the prevalence of one blood group is similarly important in other pathological conditions under multifactorial genetic influence. Some examples are set out in Table 1.

Genetic factors are known to play a part in the incidence of leukaemia, and it seems to me to be quite conceivable that they are of a multifactorial nature. I therefore studied the incidence of the ABO blood-group system in

## PSYCHOLOGY

### Effects of Age on the Recall of Dichotic Words

A RECENT report by Inglis<sup>1</sup> appears to demonstrate unequivocally that a short-term storage mechanism of the type postulated by Broadbent<sup>2</sup> is required if an individual is to recall correctly a series of dichotic digits. Furthermore, this storage mechanism becomes less efficient as age increases. Briefly, Broadbent has suggested that both perceptual and storage mechanisms are necessary in a dichotic situation. There is sequential recall, and one half of the dichotic series is held in temporary storage while the other half is being recalled. Once the first half-set has been reproduced, the stored, second half-set becomes available for recall. It is this second half-set which is subject to deterioration with advancing age. This phenomenon has been previously demonstrated<sup>3,4</sup>, but the possibility existed that these findings might also be explained in terms of other age-related changes in the nervous system. The report by Inglis<sup>1</sup> appears to preclude these possibilities. His subjects were 120 people aged 11-70. By specifying the order of recall, either before or after presentation of the stimuli, he was able to show that the results could not be attributed to age changes in perception and/or attention. That is, there was no evidence of failure to hear or to attend to the stimuli.

We have carried out a further experiment in an attempt to extend the generality of these findings. The preliminary results are reported here. The problem was to determine if non-numerical stimuli are processed in the same way as digits. That is, if an individual is presented with dichotic words, will these be recalled sequentially and, if so, will the ability to do this be related to age?

Subjects were 120 people aged 11-70. There were 20 (10 male and 10 female) in each age decade. The series of stimulus words, for example, floor, hair, grass, girl, ranged in length from one to four per half-set. The subjects were free to recall first whichever half-set they wished. This procedure was identical to earlier investigations<sup>3,4</sup>, the only difference being the nature of the stimuli.

The results were virtually identical to those using digits<sup>1,3,4</sup>. There was no significant impairment in the

ability to recall the first half-sets. There was, however, progressive and significantly greater difficulty in recalling the second half-sets as age increased. In addition, the longer the series to be recalled, the greater the overall difference between first and second half-sets.

These results are in remarkably close accord with those already cited and reinforce the notion that there is an age-related decline in the efficiency of a short-term memory storage process and this is true whether the material to be remembered is digits or words.

This work was supported by a Federal-Provincial Mental Health Grant (project No. 609-5-145). The testing was carried out by Mr. R. P. Jones.

### Hippocampal Ablation in Rats: Effects of Intertrial Interval

DEFICITS in recent memory following damage to the hippocampus have been reported in man<sup>1</sup> and in the monkey<sup>2</sup>. In a recent investigation<sup>3</sup>, we tested the hypothesis that the hippocampus is involved in recent memory functions by using different intertrial intervals in runway acquisition and extinction. The method consisted of administering acquisition and extinction trials to rats under either massed or distributed practice conditions. It was found that the temporal spacing of trials during acquisition was not important but that distributed practice trials served to increase resistance to extinction for hippocampal-damaged rats. The purpose of the work reported here was to clarify the earlier results by determining whether the extinction phenomenon was due to the spacing of trials during acquisition or during extinction. In this work, each subject received both massed and distributed trials during acquisition so that, by the end of this phase of training, all subjects had equal experience with each of the two intertrial intervals. At that time the subjects were extinguished under either massed or distributed practice conditions.

Twenty-four male rats of the Long-Evans strain were used. Age of the rats at the time of operation was 100-120 days. Twelve subjects had the hippocampus and overlying cortical tissue removed bilaterally by aspiration and 12 had cortical tissue overlying the hippocampus removed and thus served as operated cortical controls. Unoperated control subjects were not included since results of the previous investigation indicated similar performance for both operated and unoperated control subjects.

Twelve days after operation the subjects were placed on a deprivation schedule of 10 g of laboratory chow daily. Preliminary training was started eight days later and consisted of exploratory trials in the runway without food. After two days of preliminary training the subjects were

Fig. 1. Mean reciprocal latency in seconds for groups on successive days of acquisition, extinction, and reversal training. —○—, Hippocampal massed; - -○- -, hippocampal distributed; —●—, cortical control massed; - -●- -, cortical control distributed

given 10 acquisition trials on each of 6 consecutive days. Response latencies and running times were measured by timers activated and stopped by photoelectric cells. The two intertrial-interval conditions of 10 sec and 10 min were administered to the subjects on alternate days in a counterbalanced order. Thus, at the end of six days of acquisition all subjects had run an equal number of trials with each of the two intertrial intervals.

After 60 acquisition trials, the hippocampal and cortical control groups were each divided into two sub-groups which were equated for performance during acquisition. These sub-groups were assigned to 10 sec and 10 min intertrial-interval conditions, respectively. Ten extinction trials a day were carried out for six days, the intertrial interval for an animal being the same throughout this extinction period. If a subject did not reach the food cup within 60 sec, it was removed from the runway, and latency and running times for the trial were recorded as 60 sec.

It was originally planned to terminate the investigation at the end of the extinction period. However, after inspection of acquisition and extinction data we decided to continue running the rats without food but with intertrial-interval conditions for the animals reversed from those under which they had been extinguished. The rats were given 10 trials on each of 5 days under these reversed intertrial-interval conditions.

The data were converted to speed scores by taking the reciprocal of each measure for each subject. Means of the 10 daily reciprocal latency and running time measures were then computed and used in the various analyses. Analysis of variance was used with acquisition and reversal data, and analysis of co-variance with the extinction data. A level of significance of  $P = 0.05$  was used throughout. The most important results are summarized in Fig. 1 where mean reciprocal latencies in seconds are plotted for successive days. Analysis of both latencies and running times indicated that acquisition was similar for the different groups. However, during extinction hippocampal subjects showed significantly faster latencies than cortical control subjects. Further analysis indicated that those hippocampectomized animals which received distributed extinction trials showed significantly faster latencies than both massed-practice-hippocampal subjects and control animals. An analysis of extinction running times did not show any differences between the various groups.

During the period of reversed intertrial intervals, hippocampal subjects showed faster latencies than controls, but running times did not differ. Further analysis of the latency data indicated that animals with hippocampal destruction which were changed from massed to distributed

trials were significantly faster than similar animals changed from distributed to massed trials on reversal days 3, 4 and 5 but not on days 1 and 2. Thus, a significant reversal in latencies accompanying the change in intertrial intervals was not immediate but developed only after two days of running. Inspection of Fig. 1 indicates that the latencies for distributed-practice-hippocampal subjects on extinction day 6 and reversal day 5 are at approximately the same level.

Histological examination of the brains revealed extensive bilateral lesions involving the hippocampal formation and overlying neocortex in all subjects in the hippocampal group. Lesions varied in size from 50 to 85 per cent destruction of the hippocampus. Examination of sections made from animals with only neocortical lesions revealed more neocortex destroyed in these animals than in the hippocampal subjects although the total amount of brain destruction was slightly greater in the hippocampal-lesioned group.

(Further anatomical information will be supplied on request from one of us (L. E. J.).)

The results recorded here agree with our previous findings which showed no differences between hippocampal ablated and partial neocorticate subjects in runway acquisition but an increase in resistance to extinction (as indicated by latency scores) for those hippocampal-damaged animals which received distributed extinction trials. Since the procedure in the present investigation was altered so that all subjects had equal experience with the different intertrial intervals during acquisition, the slower extinction of hippocampectomized animals under distributed practice must be due to processes occurring during the extinction period. Reversing the intertrial intervals after six days of extinction resulted in an exchange of latency scores between groups of hippocampal-damaged subjects: those hippocampals which had received distributed trials during extinction developed significantly slower latencies and those hippocampals which had received massed extinction trials (and had been 'extinguished') began quickly moving out of the start box again. It is significant that the switch in latencies did not occur immediately after the reversal of intertrial intervals but appeared only after several days of running under the reversed conditions.

The present results clarify the earlier findings by showing that the slower 'extinction' of distributed-practice-hippocampal subjects is determined by partially reversible effects of a variable operating during extinction training. Further investigations will be needed to determine the specific nature of this variable. However, the present findings suggest that the temporal spacing of trials for hippocampal-damaged subjects is an important variable that should probably be taken into consideration in future studies involving this and related limbic structures.

This work was carried out while the first author was in a National Science Foundation Research Participation Programme at the University of Michigan, 1964. Additional funds were supplied by grant DA-MD-49-193-64-6120 from the Office of Surgeon General, U.S. Army, to R. L. Isaacson. We thank Sheldon Zeck for his assistance.

## FORTHCOMING EVENTS

Wednesday, July 7

ROYAL SOCIETY OF MEDICINE (at 1 Wimpole Street, London, W.1), at 5.30 p.m.—Annual Meeting.

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER IN PHARMACOLOGY—The Registrar, The University, Manchester, 12, quoting Ref. 127/65 (July 7).

ASSISTANT LECTURER IN THE DEPARTMENT OF GEOGRAPHY—The Secretary, University College, Gower Street, London, W.C.1 (July 7).

COLLEGE RESEARCH FELLOWSHIP tenable in one of the following subjects: PURE MATHEMATICS; APPLIED MATHEMATICS; PHYSICS; CHEMISTRY; GEOLOGY; GEOGRAPHY; BOTANY; ZOOLOGY; METALLURGY; ENGINEERING (Mechanical, Civil, Electrical, Industrial); and CHEMICAL ENGINEERING—The Registrar, University College of Swansea, Singleton Park, Swansea (July 10).

LECTURER IN PHYSICAL CHEMISTRY—Prof. R. M. Barrer, F.R.S., Chemistry Department, Imperial College of Science and Technology, London, S.W.7 (July 10).

LECTURER or ASSISTANT LECTURER (with experience and interest in any branch of physical research, but some preference will be given to those with interest in low temperatures, N.M.R. or elementary particles) IN PHYSICS—The Deputy Secretary, The University, Southampton (July 10).

ASSISTANT (honours graduate) IN THE DEPARTMENT OF GEOGRAPHY—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (July 11).

ASSISTANT LECTURER IN STATISTICS IN THE DEPARTMENT OF MATHEMATICS—The Registrar, The University, Nottingham (July 12).

CLINICAL PSYCHOLOGIST (Principal Grade) to take charge of the Department—The Medical Superintendent, Rampton Hospital, Retford, Nottingham (July 12).

HYDROCARBON RESEARCH GROUP STUDENT (man or woman) IN THE CHEMISTRY DEPARTMENT for research in infra-red spectroscopy—The Secretary, Royal Holloway College (University of London), Englefield Green, Surrey (July 12).

PIG INDUSTRY DEVELOPMENT AUTHORITY POSTGRADUATE SCHOLAR (graduate in veterinary science, agriculture, or a biological science) IN THE SUB-DEPARTMENT OF ANIMAL HUSBANDRY at the University of Liverpool's Veterinary Station, to participate in a research programme on the social behaviour of pigs (applications from students who expect to qualify in July, 1965, will be considered)—The Registrar, The University, Liverpool, quoting Ref. CV/135/W (July 12).

LECTURER or ASSISTANT LECTURER (with research interests in psychobiology, in personality and individual differences, or in some area of social psychology) IN PSYCHOLOGY—The Deputy Secretary, The University, Southampton (July 14).

RESEARCH ASSISTANT (with a good degree in agriculture or agricultural science, and an interest in or experience of experimental work) IN THE DEPARTMENT OF AGRICULTURE, to carry out experimental work in crop production—The Assistant Bursar (Personnel), The University, Reading, Berkshire (July 14).

ADMINISTRATIVE OFFICER (with postgraduate experience in experimental physics) to be responsible to the Professor of Physics for general laboratory administration, including academic planning and the design of the new laboratories—The Secretary, University of Lancaster, Bailrigg House, Lancaster (July 15).

RESEARCH ASSISTANT (with a good honours degree in botany and a special interest in ecology) to undertake investigations on the ecology and hydrology of Borth and Tregeon bogs—The Registrar, University College of Wales, Aberystwyth (July 15).

SENIOR DEMONSTRATOR IN PHYSICAL CHEMISTRY—The Registrar and Secretary, University of Durham, Old Shire Hall, Durham (July 15).

ASSISTANT LECTURER IN STATISTICS (in the Unit of Biometry) for duties which will involve teaching, consulting and research—The Registrar (Room 22, O.R.B.), The University, Reading (July 16).

CHAIR OF PHILOSOPHY; CHAIR OF EDUCATION; CHAIR OF GEOGRAPHY; and CHAIR OF GEOLOGY or GEOGRAPHY at Macquarie University, Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, July 16).

COMPUTER MANAGER (with organizational ability and considerable experience of computer systems) to be responsible for the day-to-day operation of a large time-sharing computing system scheduled for installation in December 1965 and for the provision of programming assistance to computer users—The Deputy Secretary, The University, Southampton (July 17).

SENIOR LECTURER and a LECTURER IN THE DEPARTMENT OF CHEMICAL ENGINEERING, University of the Witwatersrand, Johannesburg, South Africa—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, July 17).

ASSISTANT CHIEF POLLUTION AND FISHERIES OFFICER (qualified engineer or chemist, with wide practical experience of sewage works management and design) IN THE POLLUTION AND FISHERIES DEPARTMENT of the Trent River Authority—The Chief Pollution and Fisheries Officer, Trent River Authority, Meadow Lane, Nottingham (July 19).

LECTURER (graduate in medicine, microbiology, or biochemistry) IN BACTERIOLOGY—The Secretary to the College, Trinity College, Dublin, 2, Republic of Ireland (July 19).

RESEARCH ASSISTANT (preferably with experience of digital computation) IN THE DEPARTMENT OF MATHEMATICS, to work on the Murrup differential equation approach to nuclear structure, under the direction of Prof. H. A. Jahn—The Secretary and Registrar, The University, Southampton (July 19).

RESEARCH ASSISTANT and a RESEARCH OFFICER (preferably graduates with experience in computer programming in) THE COMPUTING OFFICE, to assist in computer programming arising from research in all departments of the University—The Registrar, University of Essex, Wivenhoe Park, Colchester, Essex (July 20).

SCIENTIFIC OFFICER (with an honours degree in botany, agriculture or forestry, preferably supplemented by additional study of plant pathology) IN THE PLANT PATHOLOGY DIVISION of the Ministry of Agriculture, mainly for forest pathology work—The Secretary, Civil Service Commission, Stormont, Belfast, Northern Ireland (July 20).

HEAD OF THE CHEMICAL AND ANIMAL NUTRITION DIVISION IN THE MINISTRY OF AGRICULTURE; and CHAIR OF AGRICULTURAL CHEMISTRY IN THE FACULTY OF AGRICULTURE of Queen's University of Belfast (combined post)

—The Secretary, Civil Service Commission, Stormont, Belfast, Northern Ireland (July 23).

HEAD OF THE PLANT PATHOLOGY DIVISION IN THE MINISTRY OF AGRICULTURE; and CHAIR OF MYCOLOGY AND PLANT PATHOLOGY IN THE FACULTY OF AGRICULTURE of Queen's University of Belfast (combined post)—The Secretary, Civil Service Commission, Stormont, Belfast, Northern Ireland (July 23).

ASSISTANT EXPERIMENTAL OFFICER (with a degree or equivalent qualifications) with the Soil Survey of England and Wales, to assist in mapping soils. Duties involve describing soils in the field, collecting agricultural and other data—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. 1062/70 (July 24).

CHAIR OF CHEMISTRY—The Registrar, The University, Leeds, 2 (July 25).

READER IN CLINICAL PHYSIOLOGY; and a LECTURER IN PHYSIOLOGY at Makerere University College (University of East Africa), Uganda—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (July 28).

SENIOR LABORATORY TECHNICIAN IN THE DEPARTMENT OF AGRICULTURAL BOTANY—Prof. A. H. Bunting, The University, Reading, Berkshire (July 30).

SENIOR LECTURER or LECTURER (preferably with experience in geophysics, ionospheric physics, geomagnetism, atmospheric physics, X-ray crystallography, X-ray diffraction and the analysis of molecular structure) IN PHYSICS at the University of the West Indies (Jamaica)—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (July 30).

ASSISTANT LECTURER (with appropriate qualifications and experience and specialised in physical chemistry) IN PHYSICAL CHEMISTRY at the University of Hong Kong—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Hong Kong and London, July 31).

DEAN OF THE FACULTY OF MEDICINE at Makerere University College Medical School, Kampala—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (July 31).

LECTURER or ASSISTANT LECTURER (medically qualified or non-medically qualified candidate with a special interest in immunology) IN THE DEPARTMENT OF BACTERIOLOGY—The Registrar, The University, Manchester, 13, quoting Ref. 127/65 (July 31).

LECTURER or SENIOR LECTURER IN HISTOLOGY at Massey University of Manawatu, Palmerston North, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, July 31).

SENIOR LECTURER or LECTURER (with a degree in either science or veterinary science and experience in either chemical pathology or biochemistry) IN CHEMICAL PATHOLOGY at Massey University of Manawatu, Palmerston North, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, July 31).

TEACHING FELLOW (with a good honours degree in zoology) or DEMONSTRATOR IN ZOOLOGY at the University of New England, Armidale, New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, July 31).

LECTURER/SENIOR LECTURER (preferably with research interests in control, non-linear mechanics or the dynamics of machines) IN MECHANICAL ENGINEERING at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 6).

SENIOR LECTURER/LECTURER IN EDUCATION at Rhodes University, Grahamstown, South Africa—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, August 6).

LECTURER (with an honours or higher degree and preferably some teaching experience) IN INORGANIC and/or PHYSICAL CHEMISTRY—The Director, The Swinburne Technical College, John Street, Hawthorn, Victoria, Australia (August 14).

MYCOLOGIST (graduate with special interests in the taxonomy of microfungi)—The Director, Commonwealth Mycological Institute, Ferry Lane, Kew, Surrey (August 15).

SCIENTIFIC/SENIOR SCIENTIFIC OFFICER (with an honours degree and preferably a Ph.D. or other postgraduate research experience) at the Welsh Plant Breeding Station, to take part in a research programme concerned with the development of compatible varieties of grasses and clovers, and to undertake research on associated fundamental problems—The Registrar, University College of Wales, Aberystwyth (August 31).

SENIOR LECTURER (Crystallography) IN THE DEPARTMENT OF PHYSICS, University of Cape Town—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; and The Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa (South Africa and London, August 31).

THIRD CHAIR OF EXPERIMENTAL PHYSICS (candidates should have considerable research experience in nuclear physics)—The Registrar, The University, Liverpool (September 1).

ASSISTANT CONSERVATORS OF FORESTS (nationals of the United Kingdom or the Republic of Ireland, under 45, with a degree in forestry) in Malawi, to carry out the general duties of an Assistant Conservator of Forests—The Appointments Officer, Ministry of Overseas Development, Eland House, Stag Place, London, S.W.1, quoting RC 824/134/01.

ASSISTANT LECTURER or LECTURER (or, in special cases, Senior Lecturer) IN APPLIED MATHEMATICS—The Assistant Registrar (Establishment), University of Sussex, Stanner House, Stanner, Brighton, Sussex.

ASSISTANT PHYSICIST (preferably with an honours degree)—The Secretary, Royal Free Hospital, Gray's Inn Road, London, W.C.1.

ASSISTANT PROFESSOR/LECTURER (with an appropriate degree, or higher degree, from a university in Britain and relevant teaching experience) IN VERTEBRATE ZOOLOGY at the University of Libya, Tripoli—Recruitment Division, The British Council, 65 Davies Street, London, W.1, quoting Ref. 65/UNI/67.

CURATOR (with an honours degree with geology as one of the principal subjects) OF THE DEPARTMENT OF GEOLOGY AND GEOGRAPHY—Sir John Cass College, Jewry Street, London, E.C.3.

ENTOMOLOGIST (national of the United Kingdom or the Republic of Ireland, with an honours degree in zoology or a relevant subject, plus two years post-graduate study in agricultural entomology) in Uganda, to carry out surveys and conduct research into pests of crops and stored produce, especially cotton, coffee and cocoa and to advise on control measures—The Appointments Officer, Room 301, Ministry of Overseas Development, Eland House, Stag Place, London, S.W.1.

EXPERIMENTAL OFFICER IN THE PHYSICS DEPARTMENT, to accept responsibility for the design, construction and development of instruments, involving both electronic and mechanical components, required in the Department's research programme—Prof. J. M. Bruckshaw, Geophysics Department, Imperial College of Science and Technology, London, S.W.7.

**LECTURER** (preferably with research interests) in **BIOCHEMISTRY** to teach the subject to the standard required for H.N.C. and H.N.D. in applied biology, and to assist in the development of biochemistry as part of the proposed M.Biol. and honours degree courses—The Principal, South-East Essex College of Technology, Longbridge Road, Dagenham, Essex.

**LECTURER/SR. LECTURER in FOOD TECHNOLOGY**—The Acting Principal, Royal Melbourne Institute of Technology, 124 La Trobe Street, Melbourne, Australia.

**MASTERS** to teach Physics to "O" and "A" levels and to take charge of the Department (two laboratories)—The Headmaster, Seaborough College, Yorkshire.

**RESEARCH ASSISTANT** (with a good honours degree in microbiology or biochemistry, or related qualifications, for example Diploma in Technology—Applied Biology) in the **DEPARTMENT OF CHEMISTRY AND BIOLOGY** for work in chemical microbiology—The Registrar, Hatfield College of Technology, Hatfield, Hertfordshire.

**RESEARCH ASSOCIATE** (with a good honours degree) in the **DEPARTMENT OF MEDICAL PHYSICS**, to work on the physical aspects of ultrasonics in medicine—The Secretary, Queen Elizabeth Hospital, Birmingham.

**RESEARCH STUDENTS** (with a good honours degree, or equivalent, in science or technology, though not necessarily in microbiology) in **MICROBIOLOGY**—Head of the Department of Biological and Health Studies, Battersea College of Technology Annex, 14-16 Falcon Road, London, S.W.11.

**SENIOR ANALYST** (with a degree or equivalent qualification in chemistry, agricultural chemistry or some similar subject) for the **ANALYTICAL SERVICE OF THE FACULTY OF AGRICULTURE**—The Assistant Bursar (Personnel), University of Reading, Berkshire.

**SILVICULTURIST** (national of the United Kingdom or the Republic of Ireland, with a degree in forestry, considerable research experience, and preferably a knowledge of soils and plant ecology) in Ghana, to initiate and carry out research programmes in forestry, and to train subordinate staff in forestry research—The Appointments Officer, Room 301, Ministry of Overseas Development, Bland House, Stag Place, London, S.W.1, quoting EO 824/70/1.

**TECHNICIAN** (with a I.M.L.T. qualification or City and Guilds certificate in laboratory technology, and preferably a knowledge of electronics) in a **NEW DEPARTMENT OF CARDIOLOGY**, to assist in routine work and research—The Regius Professor of Medicine, Radcliffe Infirmary, Oxford.

## GOVERNMENT POLICY AND INDUSTRIAL SCIENCE

IN his eighth Leverhulme Memorial Lecture to the Society of Chemical Industry on May 6, since published in *Chemistry and Industry* for May 22, 1965 (pp. 864-870), Mr. P. Chambers, discussing the place of the chemical industry in the development of the world's economy, was concerned mainly with the contribution of the chemical industry to the improvement of production, and only to a limited extent with the contribution which the industry could make in dealing with the problems of rising populations. Here, he was content to point out that it was desirable on grounds of self-interest, as well as on moral grounds, that the underdeveloped countries should progress more rapidly than in the past and that their standards of living should be brought with some speed nearer to those of the developed countries. Concerning productivity, he insisted on the growing scale of production and the necessity for larger economic groupings, and this was the main emphasis of the lecture.

The chemical companies with a complex of manufacturing operations starting from the petrochemical end will, in Mr. Chambers's view, tend to get larger and more international in character, because of the continuing need for very high-grade research and development on a large scale and on a co-ordinated basis. This is only economic if the costs can be spread over a correspondingly large turnover which is international rather than national in size—a point which is well illustrated by current arguments over pharmaceutical research and the cost of drugs. This view is fully supported by Prof. J. W. Mitchell in a Jubilee Memorial Lecture of the same Society on the organization of basic research for the British chemical industry. The main emphasis in this lecture, delivered in Manchester on February 12, and published in *Chemistry and Industry* for May 29, 1965 (pp. 908-935), is on the contribution of pure and applied research in increasing the value and volume of exports from those industries which depend on advances in the physical sciences for innovation and diversification. Although his theme is thus ostensibly narrower than that of Mr. Chambers, what is lost in breadth is more than gained in depth, for in an outstanding lecture Prof. Mitchell gives a most stimulating analysis of the present organization of basic research in Britain, including some penetrating criticism of educational, social and economic factors, and of Government policy and the reason for the emigration of British scientists. The whole is illuminated by a comparison of the situation in Britain with that in the United States in the light of his own considerable experience on both sides of the Atlantic.

Prof. Mitchell begins by reiterating that new knowledge is essential for industrial progress and challenging any complacency about the importance of the growth of creative science and technology for the national economy. He also insists that the vitality and attitude of mind of the research worker, his competence, and his understanding and mastery of the accumulated knowledge in his field, constitute the decisive factor for advances in scientific knowledge wherever he works. Prof. Mitchell believes that it is most desirable to separate expenditure on research from that on development, and that the administration of research should be separated from the administration of development. He gives a timely

warning that development costs can be grossly excessive if investment in preparatory and supporting basic research is inadequate, and that such inadequate research expenditure is often concealed by large total research and development costs.

Prof. Mitchell's definition of basic research is wide enough: it includes all research which leads to new knowledge. His analysis, moreover, is as clear and convincing as was that of Prof. I. D. Rattee in his inaugural lecture at the University of Leeds on "Discovery or Invention", and in this part of his lecture he seems to be thinking along similar lines. Stressing the complexity of the research problems of an industrial laboratory, Prof. Mitchell points out that careful and penetrating work on applied problems by outstanding scientists in industry has often led to discoveries of fundamental scientific importance. Here, again, he insists on the overriding importance of a stimulating and satisfying environment in which such men can work, and of enabling them to mix continuously with scientists and technologists in related fields at home and abroad.

This small creative minority of scientists and technologists, which is responsible for most new discoveries and inventions, is the key factor if we are to increase our volume of basic research relevant to the invention of new products and new processes for industry. Here Prof. Mitchell believes that Britain lags behind other countries and that this is one prime cause of difficulties in her export trade. Others arise out of the competition encountered in selling existing well-established products abroad, and here Prof. Mitchell points out that such difficulties are bound to increase as the rapidly developing countries build modern factories to supply their needs. Scientists and technologists can do no more than mitigate some of this competition, and the small size of many British firms is a further adverse factor. Nor is the position helped by limited productive capacity, long delivery times and a reputation for failure to adhere to promised schedules.

Prof. Mitchell then surveys the organization of basic research for industry and the respective contributions of the universities and colleges of technology, divisional and central industrial laboratories, Government and national laboratories, and independently sponsored research laboratories and research institutes. Each of these four groups has its own particular contribution to make, and despite the sub-title of this section of his lecture, it never suggests that academic research should be directed towards industrial objectives. On the contrary, he insists on the importance of a correct balance between creative research and teaching and that routine research should be the direct responsibility of industrial, Government or sponsored research laboratories. He is as emphatic that here, at the frontiers of knowledge, lies the distinctive contribution of the university in research as he is on the importance of the university as providing the gifted research worker and on the need for a higher staff-student ratio.

Apart from his warning against rashly dispersing a vigorous or outstanding research team, Prof. Mitchell's discussion of the function of industrial research laboratories is scarcely as pertinent to the present situation in

Britain as is his penetrating discussion of the functions of Government and national laboratories. First, Prof. Mitchell insists on the importance of the wise selection of research projects. He argues that sound advice on the selection and financial support of basic research projects can only come from outstanding scientists who are actively and continuously working in laboratories with dynamic and flourishing research programmes, which maintain their vitality and interest in advances in science and keep them aware of the level of support needed for effective work. These functions, he holds, cannot be performed by Civil Servants working alongside administrative staff in a Department of Education and Science or a Ministry of Technology, even if they have previously had some university training in science.

Prof. Mitchell does not entirely reject the idea of the part-time adviser, but late in his address he gives clear warning that a high proportion of the senior staff of the science departments of the universities cannot continue to engage in extensive external activity without seriously jeopardising the whole future of the nation, so numerous are the pressing academic problems which demand their undivided energies for urgent solution. This argument finds substantial support in any reflective reading of Mr. R. W. Clark's recent book, *Ticard*. Prof. Mitchell's own solution of the problem of advice is to put national research laboratories under the leadership of distinguished senior scientists, so staffed that they can divide their time between research and advisory and administrative work. These senior scientists would also be responsible for the objective evaluation of scientific matters of concern to the Government, based on thorough and penetrating analysis of problems and situations. One of his main reasons for challenging the decision to abolish the post of Director of the National Chemical Laboratory is that it involves the disappearance of a post for a senior scientist who might have taken a keen interest in the organization of research for British industry, stimulated by his responsibilities for running the laboratory.

Prof. Mitchell's judgment that this surprising decision is retrogressive is further substantiated by the functions and responsibilities which, towards the end of his lecture, he suggests the National Chemical Laboratory might be expected to perform. These are quite apart from three general reasons which he gives for maintaining Government and national laboratories: they can make an important contribution to continuing the education of graduates from the universities by giving them opportunities to work on research problems of national importance in contact with competent research workers while acquiring sufficient experience for independent work; they provide facilities for basic research, leading to the understanding of important national problems, which would be unprofitable for industry; and their work in establishing national standards, providing samples of chemical compounds of ultra-high purity, and measuring and evaluating their properties to provide national reference data.

Prof. Mitchell believes that greater differentiation of general functions is desirable among scientists and that it is not disadvantageous to have several groups working competitively on related problems of basic research. He is convinced that the senior members of the staffs of Government laboratories have an important and unique contribution to make to the balanced growth of science and technology, and, as already noted, he deprecates Britain's excessive reliance in the past on part-time services

of men from the universities and industry, whether in a personal capacity or as members of advisory committees. In this connexion, it should be observed that Prof. Mitchell repeatedly emphasizes the value of interchange of experienced scientists between the Scientific Civil Service and the universities and industry, but he is convinced that it is essential that there should be a sufficient nucleus of senior members from the staffs of Government institutions participating with scientists from other groups of the scientific community in Government consultations on scientific and technological matters.

This is a factor that appears to have received little attention in all the discussions on the organization of civil science during the past three years or so. He is also timely in directing attention to the social responsibility of the scientific community, and expresses the opinion that a strongly reacting scientific community has not yet been developed in Britain. Most outstanding scientists are concentrated in the universities and in the administrative sectors of the larger industrial firms, and there is little interchange between the universities and industrial laboratories. He finds none of the strong interactions and interchanges between scientists in the universities, in industry and in Government and sponsored laboratories that are found in the 25-45 age-group in the United States. The strength of the scientific community, however, is determined largely by the strength of such creative interactions as well as the quality and number of its members. Moreover, the present tendency is to increase the concentration of scientists in the universities, and neither the Robbins nor other reports on the plans adopted by the Government for the expansion of higher education appear to have directed attention to the need for balanced and co-ordinated growth in the scientific community.

Prof. Mitchell is also critical of some aspects of university expansion in Britain to-day, believing that a proper balance between teaching and research is threatened, that excessive burdens tend to be placed on senior staff and that, as regards students, the present system of examinations and selection tends to place a premium on possession of a good memory, which is no guarantee of creative ability in research. He is critical of the extent to which basic research is being undertaken in Britain to meet the needs of the medium-sized and smaller firms, and challenges Britain's concern to contract her industrial research effort when she should be reorganizing her industrial science and opening and equipping research laboratories. His comments on sponsored research and the industrial research associations may be deferred for consideration in that separate context, but his observations on the critical size and on the vitality of a research laboratory are of general validity and are highly pertinent to some recent Government decisions.

It is undeniable that responsible scientists have misgivings as to the effect of at least some of the changes already made, and Prof. Mitchell gives valid reasons for such misgivings which the Ministers concerned would do well to ponder. Moreover, he is not concerned to perpetuate any institution as such: the only true measure of the vitality of a research laboratory is its output of work of high quality, and this alone justifies the continued acceptance of the laboratory. But his insistence on the importance of a minimum critical size if a research laboratory is to be effective and productive is also related to the question of quality, on which the main stress is laid throughout the report. It is obvious that he sees real danger in a certain element of parsimony that marks

present policy. Care must be taken to ensure that the heavy burdens on senior scientists in the universities—and elsewhere—do not become insupportable for the creative minority with outstanding abilities. We can ill afford to quench their enthusiasm or diminish their creative power under the distractions of multi-functional activity.

Comparing the position of basic research in the United States and in Great Britain to-day, Prof. Mitchell attributes the greater strength of science and technology in the United States to the greater strength of the scientific community there. Federal assistance in various ways has been an important factor, together with the development of a system of graduate education in science and business management, and the consequently higher proportion of leading scientists employed in the industrial laboratories and with a wider influence. Moreover, he suggests that this greater strength of the American scientific community, and the higher standing of younger scientists, are important factors attracting many of the abler scientists from the United Kingdom, and he thinks that this continued emigration is regarded with too much complacency in Britain, especially the emigration of students from the group of Ph.D.s of average ability. Here, in Prof. Mitchell's view, the lack of openings for research with opportunities for continuing education in British industry is the decisive factor. This has been accentuated in the past two years by the closure of some industrial research laboratories and the incorporation of the National Chemical Laboratory in the National Physical Laboratory. There are, he believes, many British scientists in the United States who would return to Britain, regardless of the salary differential, if they could find non-academic posts for research which were professionally satisfying.

Prof. Mitchell does not overlook the benefits which the British scientist may derive from a period of work in the United States, but his comments on this question indicate that to some extent Britain's present difficulties are the direct outcome of Government practice and policy over the past two decades, as well as shortsightedness in industry, and that such policies and practices still persist. Policy in scientific matters cannot be guided primarily by political theory and prejudices, even when the ultimate decision is political. Nor does he omit to point out that all the efforts of scientists and technologists to resolve economic difficulties will be of little avail unless management, and those engaged in market research, and in sales, production and transport, play their full part in increasing the volume and value of Britain's exports.

The politician will scarcely find Prof. Mitchell's address comfortable reading. He rejects outright the assumption of the present Labour Government and of its Conservative predecessors that any deficiencies in basic research which are significant to the chemical industry can be rectified by supplying the universities and colleges of technology with all the laboratories and equipment and funds they need for research. This, he holds, could lead ultimately to a disastrous decline in the position of the industries based on science. The need is much deeper, and plans for university expansion must be accompanied by plans for employing the increased outflow of graduates. The place for basic research for industry is primarily in industry itself, and for this academic research is no substitute.

What is wrong is the lack of appreciation of implications of public policy where science and technology are concerned. This, as well as a lack of information, has characterized successive British Governments and their

supporters. Such information is the basis of any constructive criticism, and while this is not a specific objective of the recently established Office for Scientific and Technical Information, the new Office could assist the process, especially if the Parliamentary and Scientific Committee uses its opportunities. Prof. Mitchell refers to evidence of a widespread feeling that the formulation of policies affecting scientists in Britain is determined by small minorities, and that the scientists who will be concerned with implementing those policies are excluded from the preliminary consultations and discussions.

No effective structure for scientific and technical advice can be built up on such practices, nor are scientists of high ability and standing likely to be willing to serve under such conditions. Even if those conditions are only imagined to exist it is difficult to obtain co-operation, and the dissipation of any such atmosphere of distrust or uneasiness is a first essential. It should be followed, as Prof. Mitchell urges, by the establishment of some accepted procedure which brings into consultation the active leaders and representatives of scientists, and their professional societies, and gives them an opportunity of expressing their views before final and irrevocable decisions are made. On this point, Prof. Mitchell's analysis of the structure of advice needs to be taken deeper, and it is to be hoped that this will be done both by the Royal Society in its present examination of the situation, and by the Parliamentary and Scientific Committee. Prof. Mitchell welcomes this Committee's proposals that important matters of scientific and technological policy should be subject to public hearings by Select Committees of the House of Commons. Meanwhile, his challenge to the practice of making irrevocable decisions on the basis of secret reports and recommendations by anonymous advisers, and by confidential committees, is clear and unequivocal and in line with an important recommendation of the Commoner Committee on the integrity of science. It is not merely reasonable but vital that irreversible decisions should only be taken after the directors of research concerned have had full opportunity of expressing their own opinions and making their own recommendations on policies which would affect them. This is not claiming the right to determine policy but the right to ensure that the implications of policy are given adequate consideration. It is also the condition of responsible and dynamic leadership, and where it is not observed, policy, as well as those who dictate policy, is rightly suspect.

## HUTTON LOOKS BACK

### Recollections of a Technologist

By Prof. R. S. Hutton. Pp. 203+8 plates. (London: Sir Isaac Pitman and Sons, Ltd., 1964.) 25s. net.

PROF R. S. HUTTON'S recollections of his long and varied career have been published at a time when, apart from their interest to the numerous colleagues who have at one time or another worked or been associated with him in his several occupations, they are of some public interest in at least two connexions. First, *Recollections of a Technologist* illustrates most aptly the value of interchange between university, industry and the Civil Service which we are now belatedly trying to encourage. Prof. Hutton himself sandwiched some twenty-five years in industry in one capacity or another between two periods of academic teaching and research. Besides this, he was a founder-member of the Institute of Metals, and his recollections of his work, in and for this Institute, show the

important part which such learned societies or professional bodies can play in the advancement of technology. Secondly, the book should help to give a much more accurate and stimulating picture of the technologist in the mind of the reader and, all too short as it is, it should at least do something to assist in that urgent task of education if a sufficient number of the ablest students are to be attracted to such a career.

But to say no more would be unfair to Prof. Hutton, for the book derives added interest from his discerning comments on technical education, on the work of research associations, on the place of technical libraries and information services, and on other subjects. There is a sketch of the work of the Physics Laboratory in Manchester in the days of Schuster and Rutherford, and some more specific recollections of Schuster, Rutherford and Tizard are given in a separate chapter. As would be expected of Prof. Hutton, the references are full and well arranged at the end of each chapter.

Anyone, however, who has known and worked with Prof. Hutton will also certainly wish for more; but, suggestive as the book is and full of comments which, like those on scientific writing and the art of communication, are topical as well as wise, to those who have not known Prof. Hutton it can scarcely convey any real idea of how much we owe to him in such fields as those of technical education and the development of special libraries and information services. One may well be amazed at the range of his interests and at his untiring energy, but his work was never superficial. Prof. Hutton delved deeply in all his work and it remains for another writer to complement his own story by revealing the thoroughness and foresight of his work in the field of libraries and information services, for example, and the unfailing courtesy and deep understanding of the help he so readily and freely gave to those who turned to him for help and guidance. Inevitably in a book covering so wide a field there are points where opinions expressed might be challenged somewhat, or where small additions might seem desirable. These, however, are minor, and it is to be hoped that this readable and well-printed book will find many readers not only among scientists themselves but in industry, in Parliament and among the general public.

R. BRIGHTMAN

## NUCLEAR REACTOR PHYSICS

### Neutron Physics

By K. H. Beekurts and K. Wirtz. Pp. x + 444. (Berlin: Springer-Verlag, 1964.) 68 D.M.

### Introduction to Neutron Distribution Theory

By L. O. Woods. (Methuen's Monographs on Physical Subjects.) Pp. xii + 182. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1964.) 28s. net.

IT is now twenty-two years since the first nuclear reactor was built, and in that time reactor physics has become an established technological subject. These books represent the second generation of text-books in this field, and both can provide a very suitable basis for a university course. In fact, both books originated from such courses.

*Neutron Physics*, by Beekurts and Wirtz, is somewhat misnamed. Neutron physics as a subject is about thirty-two years old and has become diversified into several distinct areas. These include reactor physics, some parts of solid- and liquid-state physics, and some parts of nuclear physics. This book mainly covers the reactor physics side of neutron physics. With the advent of nuclear power there has been a substantial growth of interest in this area, and a number of text-books have been written. *Neutron Physics* is more broadly based than some and gives a clear and comprehensive introduction to the field. The depth of coverage has inevitably to be

limited, but adequate bibliographies are provided at the end of each chapter. The translation from the German has been carried out competently, so that almost everywhere the presentation is in good clear English. The book starts with a discussion of neutron sources, detectors and various types of experimental equipment for neutron cross-section work. It continues with the reactor physics theory and experiment, including neutron thermalization, diffusion and transport theory. The concluding section covers many of the experimental techniques of reactor physics. In the theoretical part of the book the mathematical presentation, while not particularly difficult, does require a graduate knowledge of mathematics. On the other hand, very little background of nuclear physics or knowledge of reactor physics is required. On the whole it can be recommended as an excellent introductory text and of value to university courses on reactor physics, particularly those concerned with needs of the experimental reactor physicist.

The monograph by Woods is based on a specialist course covering neutron distribution theory. Again it includes neutron thermalization, diffusion and transport theory; the mathematical presentation is slightly more difficult than in the book by Beekurts and Wirtz. For those requiring the theoretical side of the subject only, it forms an excellent introduction leading naturally to the more sophisticated theoretical treatments. Its scope is indicated by its division into three chapters; the first covers the basic equations of distribution theory, the second deals with neutron moderation, while the third covers multi-group theory. *Introduction to Neutron Distribution Theory* is a useful addition to the Methuen series and to the range of reactor physics text-books.

P. A. EGGLSTAFF

## MAGNETIC STORMS

### Solar Plasma Geomagnetism and Aurora

By Sydney Chapman. (Documents on Modern Physics.) Pp. 141. (London and Glasgow: Blackie and Son, Ltd., 1964.) 32s. 6d.

THIS monograph is one of a new series, entitled *Documents on Modern Physics*, in which the editors intend to specialize in presenting selected reviews, lecture notes, conference proceedings, and important collections of papers in branches of physics of special current interest. The contents of the book are based on lectures given by the author at the twelfth annual session of the Les Houches Summer School of Theoretical Physics in July 1962. The entire course of lectures at the School has been published previously in book form in 1963 under the title *Geophysics: The Earth's Environment*. It is rather surprising that the editors of the present monograph have not complied with the author's wishes regarding its title, as stated in his preface.

Prof. Chapman is an eminent geophysicist who has made outstanding contributions to the theory of geomagnetism. His purpose in the present book has been to describe the evolution of knowledge and theory concerning magnetic storms—the name given to intense transient disturbances in the geomagnetic field. The book may be regarded as a supplement to *Geomagnetism* (Chapman and Bartels, 1940) but, unlike the earlier treatise, the exposition is selective rather than comprehensive. Special emphasis is placed on the investigations of the author and his colleagues, notably S.-I. Akasofu and V. C. A. Ferraro. The discussion is confined primarily to researches which originated before the advent of satellites and space probes, and the reader is referred to the publications of other writers for an account of the many developments during the past decade.

The first chapter of the book outlines those aspects of geomagnetism and solar activity which are fundamental to an understanding of magnetic storm phenomena. The geometry and kinematics of the passage of solar plasma

from the Sun to the Earth are considered in Chapter 2. Several of the results obtained by the author some time ago have acquired new significance in view of present-day ideas on the extension of solar magnetic fields into inter-planetary space. Chapter 3 contains an excellent account of the early theoretical work on the interaction of solar plasma with the geomagnetic field and the more recent studies of the shape of the steady-state hollow formed in the solar plasma by the Earth's magnetic field. This chapter is undoubtedly the best available summary of the detailed investigations in this branch of the subject. The main features of magnetic disturbances are described briefly in Chapter 4. In the final chapter the terrestrial ring current is discussed in relation to the steady-state motion of a distribution of energetic charged particles trapped in a dipole field. This chapter summarizes one of the very few precise investigations of the geomagnetic effects of a symmetrical distribution of trapped radiation.

Much of the progress in the theory of magnetic storms has arisen from the formulation and solution of idealized problems in plasma dynamics. Prof. Chapman has been one of the chief exponents of this line of enquiry, and his present book provides an exemplary account of those basic concepts which form the foundations of the theory of geomagnetic storms. The book is a very valuable addition to the literature and is especially welcome at a time when speculation tends to outpace accepted theory.

D. M. WILLIS

## DESTINY OF PROTEIN

### Mammalian Protein Metabolism

Edited by H. N. Munro and J. B. Allison. Vol. 1: pp. xv + 566. 132s. Vol. 2: pp. xiii + 642. 150s. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964.)

ONE of the earlier biochemical monographs in the pioneering series, edited by Plimmer and Hopkins, was the well-known book on protein metabolism written in 1912 by E. P. Cathcart. He defined his subject as "the processes in the animal organism which are concerned with the destiny of the protein, whether of the food or of the tissues". This definition is broad enough to cover the scope of the present book, but knowledge of the destiny of protein has advanced so much that it has now taken 27 authors and 2 author-editors to deal with the subject. The whole work is divided into three parts. The first part occupies all of Volume 1 and is concerned with the biochemical aspects of protein metabolism. It opens with an historical introduction by H. N. Munro, beginning with the discovery of nitrogen and its biological consequences. This is followed by chapters on protein digestion and absorption in non-ruminants (C. Gitler) and in ruminants (A. T. Phillipson), and on free amino-acids and peptides in tissues (H. N. Christensen). H. A. Krebs deals fully with the metabolic fate of the amino-acids individually and with the ornithine cycle of urea formation. He also discusses the cause of the specific dynamic action of proteins. A. Korner deals with the mechanism of protein synthesis and A. Neuberger and F. F. Richards discuss protein turnover in the whole animal, including the problems arising in the interpretation of turnover data obtained with isotopes. This is followed by a chapter on plasma proteins (A. S. McFarlane) and there are two chapters on interrelationships between hormones and protein metabolism by J. H. Leatham and by H. N. Munro. Volume 1 ends with a chapter on nitrogen excretion by J. B. Allison and J. W. C. Bird.

Volume 2 contains parts 2 and 3 of the work, covering respectively nutritional aspects and pathological aspects of protein metabolism. Much of part 2 is concerned with protein requirements. H. N. Munro contributes an introduction and this is followed by a chapter by J. B. Allison on the nutritional value of dietary proteins and one by A. E.

Harper on amino-acid imbalances. D. M. Hegsted writes on protein requirements in general, and this is followed by chapters on protein metabolism and requirements in pregnancy and lactation (K. L. Blaxter), in the new-born (R. A. McCance and E. M. Widdowson), and in the elderly (D. M. Watkin). Part 3 opens with a general survey of pathological changes in protein metabolism (H. N. Munro), followed by a most useful chapter by L. E. Holt, jun., and S. E. Snyderman dealing with the many different congenital anomalies and acquired disturbances of amino-acid metabolism which have been described, particularly in recent years. More than 40 conditions are now known to be associated with an increased excretion of amino-acids in the urine. D. P. Cuthbertson contributes an article on physical injury and its effects on protein metabolism; then come chapters on protein metabolism in tumour growth (G. A. J. Goodlad), experimental protein-calorie deficiency (B. S. Platt, C. R. C. Heard and R. J. C. Stewart), clinical aspects of protein malnutrition (F. Viteri, M. Béhar, G. Arroyave and N. S. Scrimshaw) and, finally, one on protein deficiency and infective disease (N. S. Scrimshaw).

This outline of the contents of the different chapters gives some indication of the wide scope of the work. The list of names of the authors is enough to indicate the high quality of the book, and the editors deserve congratulation on having persuaded so many distinguished workers to join them in this enterprise. The editors have done their work of planning and co-ordination admirably, and such overlapping between chapters as they have allowed, on infant nutrition for example, is helpful rather than otherwise. They have done much to unify the whole work by inserting cross-references where necessary. It seems surprising that they have not persuaded all the authors to use the internationally recommended coenzyme abbreviations NAD and NADP (rather than the old-fashioned DPN and TPN). Only a few misprints were noticed, but one of them ('possibly' in mistake for 'possible') unfortunately makes nonsense of the quotation at the beginning of the book. There are extensive lists of references at the ends of the chapters which greatly add to the usefulness of the book. Each of the two volumes is self-contained, with its own author index and subject index. The publication of this splendid monograph is of special importance at the present time when so much effort is being devoted to studying ways of improving the quality and quantity of food protein in the many countries where there is severe shortage. It is likely to remain the standard work on the subject for a long time to come. The book will interest a wide variety of people including workers in biochemistry, nutrition, agriculture and clinical science. Its publication must have created a problem for many librarians: not whether they should order a copy, but whether the library budget will allow them to order enough copies to satisfy the demand from scientists in so many different departments.

D. C. HARRISON

## TROPICAL AND SUB-TROPICAL PLANT ECOLOGY

### Die Vegetation der Erde In öko-physiologischer Betrachtung

Von Prof. Heinrich Walter. Band 1: Die Tropischen und Subtropischen Zonen. Zweite, veränderte und erweiterte Auflage. Pp. 592 + 9 tafeln. (Jena: Veb Gustav Fischer Verlag, 1964.) 68.10 D.M.

THE first edition of this book was published in 1962 and reviewed in the April 6, 1963, issue of *Nature*. The second edition is enlarged by 54 pages; new matter consists of additional sections on competition and adaptation in Chapter 1, part of a new Chapter 3 on rain-forest of tropical mountains, a new section on the savannah

concept, a revision of two sections on the Egyptian-Arabian desert and a supplementary chapter dealing mainly with grassland and swamp vegetation in Africa.

As was noted in the previous review, Prof. H. Walter's main interest is evidently in the drier parts of the tropics, and the map showing his very extensive travels shows that he has seen little of the main areas of equatorial rain-forest. His account of that forest is based largely on von Faber's revision of Schimper, greatly reduced but with retention of many excellent photographs; only 120 pages are devoted to the ever-wet tropics. This condensation is also in part due to Prof. Walter's interest in those aspects of ecology which have been the subject of physiological measurements (transpiration, cell-sap concentration, etc.) and to his natural inclination to report his own observations of this nature; such experimental evidence is probably more abundant from the drier than the wetter tropics, where the much greater complexity of vegetation makes it difficult for the would-be ecological observer to know where to start. But, though Prof. Walter could not devote so much space as von Faber to the ever-wet regions, he could have given references to recent publications. For example, in the chapter on mangrove he describes in detail his own observations on the peculiar zonation of species on the east coast of Africa (where the salt content of the soil-water is highest on the landward side) without giving adequate information as to the very different zonation in Malaya, or any reference to Watson's careful study of it; and he fails to mention the excellent summary by van Steenis of the ecology of mangrove prefaced to the account of the family Rhizophoraceae in *Flora Malesiana* (1958). His treatment of epiphytes is brief, and in connection with the role of ants in promoting epiphytic vegetation he refers to a work of 1905, not to van Leeuwen's much later study in Java. Prof. Walter does not mention the experimental evidence that gregarious one-day flowering of some common epiphytic orchids is temperature-controlled; and he is evidently unaware of the experimental study of velamen by Dyeus and Knudson (1957) in which they demonstrate that its function is protective, not absorptive. He appears to think that *Nepenthes* are normally epiphytes, but such a condition is rare, and it is very doubtful whether most *Nepenthes* absorb much water from rain collected in their pitchers. In referring to the fern thickets which often form on poor soil abandoned after cultivation, the author mentions only *Pteridium*, whereas the important thicket-forming ferns are several members of the family Gleicheniaceae. He cites nothing later than 1910 on the biology of Loranthaceae.

Because of Treub's foresight in establishing a laboratory for visiting scientists, more experimental work has been done at Bogor (Buitenzorg) in Java than anywhere else in the Malayan region, and von Faber's work was also based on Bogor. Thus the idea has been accepted that conditions in Java, and especially at Bogor, are normal for the region, whereas the volcanic soils of Java are very different from those of Malaya, Borneo and most of Sumatra, and (for example) Gleichenia-thickets, though abundant in Malaya, are not so in Java; and the diurnal rhythm of sun and rain at Bogor is different from the very irregular onset of rain in Singapore. Von Faber also saw little of dipterocarp forest, the characteristic primary vegetation of Malaya. Prof. Walter refers to Prof. P. W. Richards on this subject, but the forest in Sumatra which is mentioned very briefly on p. 90 of *Die Vegetation der Erde in öko-physiologischer Betrachtung* is probably more representative of dipterocarp forest in general than the sample investigated in Sarawak by Richards. A good deal of work has been done since the Second World War in the countries now united in the Federation of Malaysia, and Prof. Walter could find much that is relevant to his purpose if, according to his plan, he produces a regional study of that part of the world in a separate volume.

R. E. HOLTTUM

## ELEMENTARY PARTICLE PHYSICS

### Group Theoretical Concepts and Methods in Elementary Particle Physics

Edited by F. Gürsey. (Lectures of the Istanbul Summer School of Theoretical Physics, July 16–August 4, 1962.) (Quantum Physics and Its Applications, Vol. 1.) Pp. vii+425. (New York and London: Gordon and Breach, Science Publishers, 1964.) 19.50 dollars.

*GROUP Theoretical Concepts and Methods in Elementary Particle Physics* is the first volume of a series of texts edited by R. Smoluchowski (Princeton University) on *Quantum Physics and Its Applications*. It is of a high standard and augurs well for the future of the series.

The classification of elementary particles according to group-theoretical principles is well known to be a most profitable way of correlating and understanding their properties. This has been particularly evident during the past year or so with the introduction of the  $SU(3)$ ,  $SU(6)$  and  $U(12)$  classification schemes. For this reason, the publication of this collection of lectures by many of the world's experts in the field is to be applauded. The lectures were given at the Istanbul Summer School of Theoretical Physics during July 16–August 4, 1962—before the discovery of the  $\Omega^-$  had confirmed the essential correctness of the classification of elementary particle states according to unitary symmetry. However, all the basic theory is included together with many interesting tit-bits not directly related to the main stream of advance in this subject.

The basic mathematics of Lie groups is first introduced in a masterly fashion by G. Raosh. E. P. Wigner next lectures on unitary representations of the homogeneous Lorentz group including reflexions; here, the concern is not with the symmetry classification of particles, but with the symmetry properties of the space-time continuum in which physical events occur. N. Burgoyne gives an elegant exposition of the relation between spin and statistics approached from the point of view of axiomatic field theory. A refreshing breath of down-to-earth experimental information is included in the lectures by O. W. Greenberg, who concerns himself with the bounds and relationships between total cross-sections for different elementary particle processes at high energies. L. Michel, in his lectures, stresses the importance of the study of group extensions—the relationship between different invariance sub-groups. D. Speiser lectures on the theory of compact Lie groups and makes use of the global approach due to Hopf; he also considers the problems and consequences of global symmetry in elementary particle physics.

The "Unitary Symmetry Model" is discussed in considerable and useful detail by S. L. Glashow but, perhaps even more here than elsewhere, it could be regretted that the lectures were given before the higher symmetry schemes were mooted. Y. Nambu, in an interesting set of lectures laced with a certain amount of speculation, deals with the implications of Chiral symmetries for weak and strong interactions. A very brief lecture by A. Salam looks into some of the implications of broken symmetries. Next, F. Gürsey gives an introduction to the De Sitter group with particular reference to the implications of a De Sitter space for elementary particle physics. The volume ends with three short contributions by E. Inönü, O. W. Greenberg and E. R. Caianiello dealing respectively with the contraction of the Lie groups, parastatistics and the renormalization group.

The notes presented in this volume all seem to be carefully prepared, and it is clear that in many cases the presentation and content have greatly benefited from discussion and criticism during the Summer School itself. Each contribution is well worth-while and the overall impression given by the volume is excellent. One can only regret that it could not have been produced a little more cheaply.

R. J. BLIN-STOYLE

**New Methods of Analytical Chemistry**

Second edition. By R. Belcher and C. L. Wilson. In association with T. S. West. Pp. xv+366. (London: Chapman and Hall, 1964.) 60s.

THE United Kingdom can boast of only three university professors of analytical chemistry, and when they all collaborate in the revision of a well-known book it is certain that the work will possess that *sortor resartus* quality which signposts an improvement in its scientific and didactic value. This expectation is fully borne out by this second edition.

The first chapter deals individually with the more common titrimetric acid-base standards and then considers those of more recent origin, for example 4-aminopyridine for acids and sodium hydrogen diglycollate for bases. Oxidation-reduction standards such as cupric oxide or barium thiosulphate are also briefly considered.

Indicators of all types, chemiluminescent, screened, redox, metallochromic, etc., are all lucidly dealt with in the second chapter. A detailed account of titrant usages then follows, for example the use of sodium chlorite; ferricyanide procedures; potentiometric titrations of hydrazine; use of *N*-bromosuccinimide, etc.

Newer organic and inorganic precipitants form a most valuable section of this book, although they can only receive brief mention here. Selected spectrophotometric methods from recent literature are presented in much detail, for example, the arsenazo method for hafnium; and the pyrogallol red procedure for silver ion. Precipitation from homogeneous solution receives adequate treatment, four specific procedures being mentioned. The powerful techniques of solvent extraction receive full coverage, simultaneous extraction and direct analysis being sometimes possible.

The final chapter presents a survey of miscellaneous analytical methods which will titillate the palates of both the classical and the more sophisticated analyst. The gravimetric determination of fluoride and the titrimetric determination of barium sulphate are typical of the many analyses lucidly covered in this section.

This edition of *New Methods of Analytical Chemistry*, even more than its predecessor, will be a welcome addition to the libraries of analysts everywhere. The lecturer, teacher and practising analyst will all derive much instruction and help from this up-to-date authoritative discussion and presentation of the newer reagents and of recent methods.

D. T. LEWIS

**Coulomb Wave Functions**

By A. R. Curtis. (Royal Society Mathematical Tables, Vol. 11.) Pp. xxxv+209. (Cambridge: At the University Press, 1964. Published for the Royal Society.) 80s. net.

COULOMB wave functions arise in the solutions of Schrödinger's equation for an electron in a central field. The U.S. National Bureau of Standards published tables of these functions in 1952 (Applied Mathematics Series No. 17), and other tables are also known.

In 1950, the late Prof. D. R. Hartree and others proposed to the Royal Society Mathematical Tables Committee the preparation of tables of these functions, and the present volume is the outcome of their proposals. An attempt was made to choose solutions of the differential equation which are not only mathematically linearly independent but also numerically distinct, and at the same time to produce tables which are readily interpolable in the energy parameter. These two requirements are not entirely compatible, and the final choice of solutions is to some extent a compromise.

*Coulomb Wave Functions* contains a mathematical introduction, a useful collection of formulae concerning the selected standard solutions, instructions for the use of the tables, and a bibliography. The tables themselves give values of the selected solutions of the differential equation  $y'' + [a + 2x^{-1} - L(L+1)x^{-2}]y = 0$  for  $L = 0$ ,

1, 2;  $-2 \leq a \leq 2$ ; and  $0 \leq x < \infty$ . For  $x \geq 10$ ,  $x^{-1}$  is used as the tabular argument. The tables are reproduced photographically from sheets prepared on a card-operated typewriter.

**Chemotaxonomie der Pflanzen**

Eine Übersicht über die Verbreitung und die Systematische Bedeutung der Pflanzenstoffe. Von Prof. R. Hegnauer. Band 3: Dicotyledoneae: Acanthaceae—Cyrillaceae. (Chemische Reihe, Band 18.) Pp. 743. (Basel und Stuttgart: Birkhäuser Verlag, 1964.) 123 Sw. francs.

WITH Volume 3 of *Chemotaxonomie der Pflanzen* begins the treatment of the large group of Dicotyledoneae which is covered as far as Cyrillaceae. The first few chapters contain a survey of the chemistry of alkaloids common in this group. They are subdivided into protoalkaloids or biogenic amines, pseudoalkaloids like terpenes, purines, and derivatives of nicotinic acid, and into alkaloids themselves. The pathways of biosynthesis of larger structures from simple amino-acids are schematically outlined.

The Dicotyledoneae include many plants of great medical and toxicological interest, of which a few examples may be mentioned. To the Apocynaceae belong compounds of the yohimbine-, reserpine-, strychnine-, and cantharidin-types, and strophanthin. Quaternary ammonium bases with curariform action are present in Cappariaceae, and salicin is found in Caprifoliaceae. Hallucinogens are discussed in connexion with several families; *Lophophora williamsii*, the Mexican peyote, is a well-known example, and for *Cannabis sativa* the chemical relationship between antibiotic and bactericidal actions and intoxicating effects is outlined. The pathways of synthesis of norephedrine in *Catha edulis* may be similar to those of ephedrine in Ephedra. Chinese and Japanese medicine uses plants of the Asarum family, the identity of which is not fully established. Derivatives of the anthelmintic pelletierine have been found in the Crassulaceae.

Of general interest are the Asclepiadaceae which contain arrow poisons, and the Annonaceae in the seeds, leaves and roots of which substances of an unknown type act as contact poisons against aphides.

Though the literature is considered until the end of 1963, the author states that Volume 3, unlike its predecessors, does not contain a complete survey of the known facts, since for some families, like the Apocynaceae, the phytochemical literature is very large and readily available in modern standard works. Even so, the volume presents in a clear manner a wealth of information on a field of wide interest.

**Scientists as Writers**

Edited by James Harrison. Pp. 206. (London: Methuen and Co., Ltd., 1965.) 21s. net.

*SCIENTISTS as Writers* is essentially an annotated anthology of prose passages written by scientists, mostly of the present century, arranged around eleven themes, including the nature of the universe, of matter, of life, of mind and of science, evolution and man, the laws of chance, science and art, and science and religion. They are linked by explanatory notes and comments, and there are a few suggestions for further reading. The book is intended for use in general courses in sixth forms and elsewhere, to further both the command of English and the broader understanding of science. While it illustrates admirably that scientists can and do write about their work lucidly and in impeccable English, it seems to achieve its second purpose of interpretation even more effectively than the selection of similar excerpts edited by S. Rapport and H. Wright and published two years ago under the title *Science: Method and Meaning*.

## IMPOTENCE AND ACHIEVEMENT IN PHYSICS AND TECHNOLOGY\*

By PROF. R. V. JONES, C.B., C.B.E., F.R.S.

Department of Natural Philosophy, University of Aberdeen

AMONG the most lasting of Lord Cherwell's many interests was the principle of indeterminacy. And among the most permanent of his dislikes was any suggestion of defeatism. When I became one of his students in 1930, he was applying the indeterminacy principle with great enthusiasm; and I was alongside him in 1940 at the climax of his pre-war fight against defeatism in national defence. My own outlook was enriched by both these experiences, which were all the more fascinating because of the apparently different attitudes of Lord Cherwell—in one case the close ally of Winston Churchill in utter rejection of defeatism, and in the other the ready acceptor of the limits that Nature appears to place on human powers of observation.

Let me also acknowledge my debt to Sir Francis Simon. Just as Lord Cherwell had become engrossed with one postulate of impotence, the principle of indeterminacy, so Simon was fascinated by another, the third law of thermodynamics; and Simon, an artillery officer against Britain in the First World War, stood very firmly with Britain in the Second. His name was among those of British citizens to be rounded up by the Nazis if "Operation Sea-Lion" had succeeded; and I must now confess that this may have been due not only to his own eminence but also to a hoax that I extemporized on an agent of the German Secret Service whom I found wandering around the old Clarendon Laboratory in 1935, and whom I persuaded (in an effort to distract his attention from some air defence equipment) that there was a great anti-Nazi organization in Britain with Simon at its head. I hope that Simon forgave me—especially since I stand indebted to him for support at important stages in my own career.

In *The Physical Significance of the Quantum Theory*, Lindemann<sup>1</sup> quotes the futility of trying to describe the smell of nitric oxide, which is changed to nitrogen peroxide when it is drawn with air into the nose of the observer. Such a process is a self-frustrating one, and it can have similar results to impotence; and so, before considering principles of impotence, let us look at self-frustration. It is an important aspect of modern life, especially in human relations; and, had we thought about it more, we might have avoided many errors of administration.

Lord Cherwell, for example, during the War held a pass that was intended to allow him to enter any Government establishment. Such a universal and vital pass could only be issued to persons of extreme responsibility; most people held passes which would admit them to only one specific establishment. Since there were few persons of comparable responsibility to Lord Cherwell, there were very few of his kind of pass; and its appearance was kept confidential, so that it could not easily be forged. It followed that very few guards at the entrances to establishments had ever seen it, and so Lord Cherwell had great difficulty in persuading them that it was genuine, and to let him in.

Self-frustration can arise very easily in military security. An example which I remember particularly well occurred in the German Air Force towards the end of 1940, when Goering realized that by some means we often knew in advance where his night bombers were going to attack. He therefore ordered an intense search throughout the Luftwaffe for the means by which information was

leaking out. Fortunately for us, the search failed—the radio beam stations for guiding the bombers, which were the actual source of the leak, were at that time so secret that they were specially exempted from the scrutiny of the investigating officers.

In war, one sometimes tries to deceive the enemy; and in doing so may give away the very thing one is trying to hide. In the First World War, for example, British Army radio messages were encoded by a system which was changed daily, but which was used not only for operational signals but for practice messages as well. So that the latter could be distinguished from the former, and not taken seriously, each practice message was prefixed by the name of some animal. This step provided the German cryptographers with what they needed—a 'crib'. All they had to do was to examine our practice messages and try one animal name after another until they found a consistent encoding system: they could then simply read our operational signals.

As an example in which the roles were reversed, I may perhaps mention our estimates of German rocket production before the V2 campaign in 1944. One vital step in our argument was to estimate the numbers of rockets which the Germans intended to store in forward areas in France. Now these stores were extremely difficult to locate and we found only a few of them; in addition, the Germans had built dummy storage sites to divert our attention. The dummies were, of course, made easy to spot from the air, and we found them all quite quickly. Then, by luck, we captured a map which showed the genuine sites west of the Seine, with their capacities. Most of the genuine sites, however, lay east of the Seine, and we did not know where they were; but we did know the numbers of dummies both east and west of the Seine. Thus, assuming that the Germans had disposed the dummies in consistent proportion to the genuine sites, we could estimate the number of genuine sites east of the Seine. This reasoning produced easily the closest estimate<sup>2</sup> of the intended rate of fire: we could never have made it if the Germans had not tried to deceive us.

Notorious as producing a result opposite to the administrative intention has been the 'costs plus' system of paying firms for Government work. 'Costs plus ten per cent' appears to be a very reasonable price to pay, until one realizes that the manufacturer is automatically tempted to inflate his costs by any legitimate device, since he is thereby improving his profit. And if his nominal profit margin is unreasonably small—at the point, for example, where he would do better to sell his plant and invest his shareholders' money in another industry—then the Civil Servants who have to supervise the contract, and who know that the job must be done and the manufacturer of vital defence equipment kept in business, will turn a lenient eye on over-estimates of the manufacturer's costs. Thus, a system which at first sight appears fair and economical works out in practice to be extravagant and demoralizing.

We are becoming painfully acquainted with self-frustrating situations in education. A subject such as physics can prove vital to national survival, both in defence and in industry. When this happens, more physicists are demanded by Government establishments and industry, and so there are fewer left to staff the universities and the schools. Teaching then becomes more unattractive at all levels, owing to the increased

\* Substance of the sixth Cherwell-Simon Lecture delivered in the University of Oxford on May 18.

load, and so more men leave teaching; the output of graduates thus tends to fall in those very subjects in which the national need is greatest, while it rises in those subjects which are less vital. An educational system in this phase is like an internal combustion engine starting from cold—if the throttle is opened too quickly, the mixture gets too weak in fuel, and the system stalls.

Another way in which self-frustration can occur in education was exemplified by the French, when they set their academic standards very high. The difficult examination standards frightened away students, even those who might have attained them, with the result that the subjects with high standards were weakened instead of strengthened.

Even when all academic examinations are past, there remain further dangers. One of these is election to learned societies, where in some instances the candidate has to be supported by as many as six existing members. While this is apparently a very healthy check on the standing of the candidate, it gives an advantage to candidates who work in centres where there are already six members, and this can make for inbreeding rather than health.

It could be salutary to extend this catalogue of self-frustrating actions. The University of Oxford Union "King and Country" motion of 1933 made it more likely rather than less likely that those who voted against fighting would ultimately have to fight<sup>3</sup>. In Intelligence, it is almost as dangerous to watch one's enemy too closely as not to watch him at all—the watchers can become bored, or gradually acclimatized to the posture of the enemy, so that they fail to detect the imminent blow. This happened to us in the escape of the *Scharnhorst* and *Gneisenau* through the Straits of Dover, and it nearly happened again in June 1944 when, after a year of watching the flying bomb, we only just succeeded in overcoming the boredom of routine in time to detect the forward passage of the bombs to the launching sites<sup>4</sup>.

At the very least, an essay on self-frustration would be a valuable addendum to *Microcosmographia Academica*, since it provides one of the few lines of effective argument in the misconduct of academic business that was overlooked by F. M. Cornford<sup>5</sup>. The phenomenon usually arises because the administrator has applied the wrong criterion to regulate the situation with which he has to deal.

There is often peculiar humour about self-frustration. Humour itself is generally associated with incongruity<sup>6</sup>, and the element of incongruity in this case springs from the fact that we subconsciously recognize that true achievement requires both thought and work—the greater the achievement, the more the thought and work that have to go into it. When, instead, the extra thought and work result in frustration of the original aim, then we have an incongruity, and the rudiment of a comic situation.

Consider, for example, a train of events which started outside the old Clarendon Laboratory, Oxford. I came across a dirty beaker full of water just when I happened to have a pistol in my hand. Almost without thinking I fired, and was surprised at the spectacular way in which the beaker disappeared. I had, of course, fired at beakers before; but they had merely broken, and not shattered into small fragments. Following Rutherford's precept I repeated the experiment and obtained the same result: it was the presence of the water which caused the difference in behaviour. Years later, after the War, I found myself having to lecture to a large elementary class at Aberdeen, teaching hydrostatics *ab initio*. Right at the beginning came the definitions—a gas having little resistance to change of volume but a liquid having great resistance. I thought that I would drive the definitions home by repeating for the class my experiments with the pistol, for one can look at them from the point of view of the beaker, thus suddenly challenged to accommodate not only the liquid that it held before the bullet entered it,

but also the bullet. It cannot accommodate the extra volume with the speed demanded, and so it shatters. The experiment is rather a messy one to do in a lecture room; but, as Clerk Maxwell had said of his own hydrostatic experiments to the predecessors of this same class many years before, "We were not very wet"<sup>7</sup>.

The experiment became duly public in Aberdeen, and inspired the local Territorial contingent of the Royal Engineers, who used sometimes to parade on Sundays to practise demolition. One task that fell to them or, more accurately, refused to fall to them, was the demolition of a tall chimney at a local paper works. There are various standard procedures for this exercise, one of the oldest being to remove some of the bricks of one side, and to replace them by wooden struts. This process is carried so far as to remove the bricks from rather more than half-way round the base of the chimney and to a height comparable with the radius. A fire is then lit in the chimney, to burn through the struts and cause the chimney to fall.

The Royal Engineers, however, decided this time to exploit the incompressibility of water as demonstrated by my experiment. Their plan was to stop up the bottom of the chimney, fill it with water to a height of 6 ft. or so, and simulate the bullet by firing an explosive charge under the water. Since diversions on the Sabbath were rare in Aberdeen, the exercise collected a large audience and the charge was duly fired. It succeeded so well that it failed completely. What happened was that, as with the beaker, every brick in contact with the water flew outwards, leaving a slightly shortened chimney with a beautifully level-trimmed bottom 6 ft. up in the air. The whole structure then dropped nicely into the old foundation, remaining upright and intact—and presenting the Sappers with an exquisite problem.

Here again, in technology as well as in administration "the best laid schemes . . . gang aft a-gley" through some element built into the original plan. As a passing example, we may note the failure of all attempts to make a golf ball attain maximum range by polishing its surface. There is a story that P. G. Tait, then professor of natural philosophy in the University of Edinburgh, calculated the maximum range of a golf ball, and that his son then took him out on the links and showed him that the ball could be driven much further. It was also said that old balls went further than new ones. This was probably true, because the surfaces of old balls were chipped and roughened; and, based on this observation, new balls have ever since been intentionally dimpled. The then unknown factor which later came to light in the wind tunnel was that the roughness encouraged the onset of small-scale turbulence around the ball, and—over the useful range of velocities—this forestalled and obviated the large-scale and more dissipative turbulence which would occur when the laminar flow around the smooth ball ultimately broke down. Rough balls thus have less resistance, paradoxically, than smooth ones<sup>8</sup>. There is probably a lesson for the administrators here as telling as anything in classical politics.

As an antithesis to the self-frustrating regulation, we might examine the self-fulfilling prophecy. When, for example, Winston Churchill said in 1940 that "we shall never surrender" he did by his very words make our surrender more unlikely. But this avenue would lead away from our main course, which must head past Sancho Panza, pondering over the self-negating prophecy of the man who came to be hanged on the bridge<sup>9</sup>, towards principles of impotence.

The phrase is a relatively new one, invented by Sir Edmund Whittaker<sup>10</sup> in his presidential address to the Royal Society of Edinburgh in 1941; but the axiomatic method of thought that it implies is very old, going back at least to Heraclitus with his "You cannot step into the same river twice" because the water in the river will be different on the second occasion.

There is great fascination in the axiomatic approach, especially when the axiom is one of renunciation and when what follows from it is a gain in understanding comparable with what has been voluntarily renounced. It is almost like the battle between the angel and Robert of Sicily<sup>11</sup>, with the humble and meek being exalted after the final act of submission. Perhaps it was this aspect that appealed to Aristotle so much, for he was prepared to admit several principles of impotence; it was impossible, he held, to create a vacuum, an infinite universe, or a plurality of worlds<sup>12</sup>. The last two of these were largely a matter of metaphysics, but the first was a good working approximation to reality. In fact, in the old Clarendon Laboratory we sometimes thought that "Nature abhors a vacuum" should be our Laboratory motto, so much time did we spend looking for leaks. But Aristotle used the principle far more elegantly in disposing of an uncomfortable paradox which upset ancient dynamics. Based on the observation that bodies stop moving if the pushing agent were removed, a law was formulated that "what-ever is moved is moved by another". This was convincing enough so long as it was applied to bodies being moved over rough surfaces, but it encountered trouble when applied to the flight of an arrow. What could be moving the arrow, once it had left the bow? The ingenious answer was that the arrow and the air interacted; the head of the arrow pushed the air into motion, and this air then circulated around the arrow, blew up its tail, and so drove it along. On this theory, the air was essential to the flight of the arrow, which should thus cease to fly if it were in a vacuum. At the same time, there was also the matter of experience that the less the resistance, the faster a body moved. Since a vacuum could be expected to have no resistance, it followed on this basis that a body should move through it very fast indeed. Faced with this paradox of a plausible hypothesis producing exactly contradictory results through two different chains of argument, Aristotle skilfully argued that this showed that a vacuum could not exist<sup>13</sup>. He was here, incidentally, approaching the modern idea of it being sensible to talk only of phenomena that could be observed.

The Aristotelian principles of impotence survived until A.D. 1277, when they were rejected by a Council of Paris<sup>14</sup>; and in the following six centuries the rejection was increasingly justified by events. It was found possible to make a good working vacuum; and science was refounded on the much sounder and more positive basis of Newton's Laws.

Gradually, however, principles of impotence have come back, starting most clearly with the second law of thermodynamics, first formulated by Clausius and Kelvin about 1850. This law codified a wide range of practical experience, such as the impossibility of increasing the brightness of a source of light simply by means of an optical system<sup>15</sup>. This fact was evidently unknown to two workmen in Portsmouth dockyard who, in my time with the Admiralty, sent to the Inventions Branch a proposal to make a very bright searchlight by focusing the image of a carbon arc successively from one ellipsoidal mirror to another until the final image fell back on the arc, and so made it twice as bright as before. Then the enhanced light was re-focused around the system back again on to the arc, the brightness of which was therefore redoubled. When the process had gone far enough, the light was to be let out of the system into the searchlight beam. A formal letter was sent to the workmen from the Admiralty, thanking them for their proposal, and begging to state that Their Lordships considered that it would not work since it contravened the second law of thermodynamics. There came back an apologetic letter saying the proposers had had no idea that they had been breaking any of Their Lordships' regulations, but they still believed that their invention would work. The issue was neatly settled by the Admiralty making a grant of £50 to the workmen to try their ideas out, this measure being held cheaper and better for

morale than a prolonged correspondence. From the subsequent silence, the second law eventually triumphed.

While the second law, as formulated either by Clausius or Kelvin, was a definite postulate of impotence, it was perhaps not at first clear that the first law could be expressed in a parallel way. But in 1877 Maxwell<sup>16</sup> put it in the following form: "The total energy of any material system is a quantity which can neither be increased nor diminished by any action between parts of the system . . .", and this is sometimes popularly expressed as "it is impossible to create or destroy energy". Since we thus have a great conservation law re-expressed as a postulate of impotence, it follows that other conservation laws (including the newest ones in high-energy physics) could be expressed in a similar way. For example, the conservation of momentum can be re-expressed as 'it is impossible to change the total momentum of a system by any action between its parts' or 'it is impossible to move the centre of mass of a system by any action between its parts'. It is sometimes helpful to have the conservation laws framed in this negative way, although it is more likely that they arose in the minds of their discoverers in searching for quantities that were positively conserved.

An important quantitative law which was first deduced from a negative experiment was that of the inverse square law in electrostatics. This experiment, first reported by Franklin and appreciated by Priestley<sup>17</sup>, showed that it was impossible to detect any electrostatic force on an isolated charged body inside a charged hollow conductor. Whittaker<sup>18</sup> has stated that this, along with another postulate of impotence ("it is impossible to detect a uniform translatory motion, which is possessed by the system as a whole, by observations of phenomena taking place wholly within the system"), can be used to deduce the inverse square law for charges at rest, and then (by considering these charges in motion relative to the observer) the existence of magnetic force, and thence Maxwell's equations.

Historically, however, things did not evolve that way. Maxwell found his equations by quite different arguments; and, forty years later, Einstein was troubled by the asymmetry to which they apparently led in the actions between a magnet and a conductor, depending on which of the two was supposed to be in motion. Einstein<sup>19</sup> later explained in his autobiography:

"... I despaired of the possibility of discovering the true laws by means of constructive efforts based on known facts. The longer and more despairingly I tried, the more I came to the conviction that only the discovery of a universal formal principle could lead us to assured results. The example I saw before me was thermodynamics. The general principle was there given in the theorem: the laws of nature are such that it is impossible to construct a perpetual mobile (of the first and second kind). How then could such a system be found? After ten years of reflection such a principle resulted from a paradox that I had already hit at the age of sixteen. . . ."

Following Hume and Mach in examining the nature of observations, Einstein thrust his way to a new postulate of impotence, the impossibility of detecting, in a system in uniform motion, any change in the velocity of light *in vacuo* whatever the speeds of the source and observer. Combining this with the independence of the laws of mechanics from the choice of inertial system, he arrived at the special theory of relativity. By accepting man's impotence to observe absolute uniform motion, he grasped extraordinary prizes, such as an understanding of the increase of mass with velocity and, above all, the discovery of the equivalence of mass and energy. Incidentally, he also showed that this equivalence followed from Maxwell's equations, coupled with momentum conservation when expressed as an impotence to move the centre of mass of a system by action between its parts.

Shortly before Einstein's work, Planck had found that it was at last possible to understand the black-body radiation curve if one assumed that radiation took place

in jumps, governed by his mysterious quantum of action  $\hbar$ . Twenty-five years later, Heisenberg<sup>19</sup> showed that this constant expressed an apparently inevitable uncertainty in any simultaneous measurements of conjugate coordinates, such as the momentum and position of a particle, so that the product of the two uncertainties was itself, on average, equal to  $\hbar$ . Thus, if one accepts man's inability to perform experiments of unlimited precision in this respect, and acknowledges an inevitable degree of imprecision defined by the uncertainty relation, explanations for many of the mysteries of atomic physics can be found, and puzzles in the behaviour of observing instruments understood. Similarly, once the impossibility of distinguishing one electron from another is admitted, the nature of the homopolar bond in chemistry becomes evident; and theoretical chemistry has benefitted from the postulate that interested Simon so much, the unattainability of the absolute zero.

The determinacy arguments, enthusiastically developed by Lindemann, made much impression on those of us who were his students around 1930. And it was the good fortune of some of us to be actually present at the birth of another postulate of impotence, at a colloquium by E. A. Milne in Wadham College. In preparing a talk on the red shift, he was struck by the possibility of a completely new cosmology, starting from the assumption that there was no observation by which any man could tell that he was not at the centre of the universe; in this cosmology<sup>20</sup> all other observers would appear to be receding radially away from him, at distances proportional to their velocities. This principle can be more simply stated as "it is impossible to tell where one is in the universe"; and to this Bondi and Gold<sup>21</sup> in 1948 added the further postulate that "it is impossible to tell the cosmic time"—from which the hypothesis of continuous creation results. While these last two postulates have scarcely given rise to any 'useful' results, they have stimulated a great deal of thought; and Milne's method of distance measurement by light signals in a way anticipated radar.

A postulate of impotence, to have value, must state something much more than is self-evident—it is of little profundity, for example, to say that it is impossible to find an integral power of three that is divisible by two. (It may be of intermediate profundity to say that no perfect model of a new phenomenon can be made, and that all 'explanations' must be partial only.) A valuable postulate usually codifies, and extrapolates from, a great deal of practical experience in which something has been attempted by many routes, and all of them have resulted in failure. The postulate supposes that this failure is due to something inherently impossible about the thing being attempted, such as the detection of drift through the ether. The value of the postulate arises in two ways: it can then act as our guide to save us wasting further time on impossibilities such as perpetual motion engines, and it can enable us to think intelligently about other phenomena the explanation of which is otherwise obscure. It may even enable us to predict them as, for example, the uncertainty principle tells us at once to expect that long decay times will be associated with very sharp transitions.

The successes of postulates of impotence have made physicists the readier to formulate them, and have encouraged the axiomatic approach. E. T. Whittaker, indeed, looked forward "to a time in the future when a treatise in any branch of physics could, if so desired, be written in the same style as Euclid's *Elements of Geometry*, beginning with some *a priori* principles, namely, postulates of impotence, and then deriving everything else from them by syllogistic reasoning".

While Whittaker thought that this would apply especially to branches of physics "in a highly developed state", there has been an increasing readiness to set up postulates of impotence in advance of experimental evidence. The logical consequences of a postulate are

then evaluated, and experimental checks made in order to test its validity. This is a legitimate enough procedure, especially since it may stimulate experiments that would otherwise not be known; but the too ready postulation of impotence can be a danger to progress, especially in technology. It is this aspect that I now want to discuss.

My first cautionary example, curiously, is the very one which Whittaker cited as the prototype of postulates of impotence, and concerns the possibility of recognizing the two components of a double star with an astronomical telescope. It was found in the eighteenth century that this problem presented experimental difficulties due to the broadening of the individual images, and in 1823 Fraunhofer showed that the size of the star image in a telescope is inversely proportional to the aperture of the object glass. The blurring of the image is, of course, due to diffraction, and Fraunhofer's work led to the theory of the resolving power of optical instruments.

The subject was investigated—above all—by Rayleigh, who showed that the theory could be applied to the sharpness of images produced by any optical system; and, among other aspects, he evaluated the possibility of detecting very small rotations of a galvanometer by observing the reflected image from a mirror attached to the suspension. He came to the conclusion that a rotation of the mirror could be recognized by a movement of the image, provided that the rotation of the mirror was enough to move its edges through a distance equal to one quarter of the wave-length of the light which was being used to form the image. It was, incidentally, at the meeting of the British Association for the Advancement of Science in Aberdeen in 1885 that he announced this result<sup>22</sup>. It has been much quoted since.

So here we have a postulate of impotence, that it is impossible to detect the rotation of a mirror, unless its edges move by at least a quarter of a wave-length. In practice<sup>23</sup>, it is not difficult to observe rotations of the mirror that correspond to movements of one-millionth of this value. The reason is that the postulate is false. Of course, there is something behind it. The formula for resolving power is reasonably near the truth, but resolving power is a criterion that applies to recognition of two images simultaneously, when both are present, in an optical system. This, however, is not the problem involved in observing the rotation of a mirror. In the former case, we have to observe the presence of two diffraction patterns simultaneously, and to recognize that there are two present, whereas in the second case—the rotation of a mirror—we have to establish the centre of the diffraction pattern before the mirror is moved, and compare its position with that of the centre of the pattern after the mirror has moved. This is a very much easier problem, and the postulate of impotence of resolution no longer applies—we can do a million times better.

The confusion between resolution and precision extends over a wide field. I even encountered it in 1940, when one of our most distinguished physicists could scarcely believe that the Germans could set up a radio beam system over Britain with the precision that I had stated. His argument was that the resolving power of the aeriels used by the Germans would not allow the accuracy of alignment that would be needed. Fortunately, the problem was almost exactly the same as that of the galvanometer mirror, and I was able to convince him.

Radio has indeed been a field where false postulates of impotence have flourished, from the days when Marconi astonished many men of science by signalling across the Atlantic so far around the curvature of the Earth that he appeared to defy diffraction theory. The theory was, of course, reasonably correct—but in practice there was a new phenomenon that few had foreseen, reflexion by the ionosphere. Much later, it was difficult to make authorities in Britain take seriously the radio-navigational means of blind bombing being developed by the Germans—again

because it was thought that these means would have a shorter range than in fact they had.

We had in 1940, incidentally, almost given up hope of developing an airborne radar equipment for detecting towns, because we believed that it would require centimetric wave-lengths to give the necessary accuracy (which was correct) but that metric wave-lengths would be necessary to differentiate between the buildings in a town and the incidental irregularities of open country. We were therefore almost leading up to a postulate that it would be impossible to detect towns by radar from the air. Actually, there is always moral comfort when one concludes that some form of military nastiness is excluded by Nature; but for this very reason one needs to be very careful before concluding that it is indeed so. One must apply what in English studies<sup>24</sup> is known as 'Crow's Law', after Mr. John Crow, of King's College, London: 'Do not think what you want to think until you know what you ought to know', and which was anticipated by Pasteur's<sup>25</sup> 'I should like to see these profound words inscribed on the threshold of all the temples of science: 'The greatest derangement of the human mind is to believe in something because one wishes it to be so'".

To return to radar bombing: it was quite by accident that we found that towns showed up very well in centimetric airborne radar. The missing factor in our previous thinking was the presence of many corner-reflectors constituted by the vertical and horizontal surfaces in a typical town.

The development of centimetric radar was itself a triumph over another false postulate of impotence: that it was impossible to generate much power at wave-lengths shorter than about fifty centimetres. This was a doctrine when I was first concerned with air defence in 1935. The argument ran thus: the period of the shortest waves which it was possible to generate must be longer than the time that it took electrons to cross from the cathode to the anode of the generating valve. Now this argument was quite bogus—once again the wrong criterion was being watched. I first realized this through a comic incident at Farnborough, when a long-range loudspeaker was being demonstrated to the Air Staff. The origin of the demonstration was a desire for a more humane way of policing the tribesmen of the North West Frontier than bombing their villages. The idea was that instead an aeroplane should fly over the village and address the inhabitants through a loudspeaker. It was hoped that, both aircraft and loudspeakers being new weapons, the tribesmen might be awed into submission by the voice of God. Such a powerful loudspeaker was novel not only to the tribesmen—it did not exist at all, and had to be specially made. It was set up on one side of the aerodrome at Farnborough, and actuated by a microphone on the other side. You could thus speak into the microphone, and two or three seconds later your voice would come booming back to you from the other side of the aerodrome. On the day of the demonstration, the Air Staff representatives were as much impressed by the novelty as were the prospective victims. Before long, one of them, on hearing his own voice for the first time in this curious way, laughed. After the due interval, the loudspeaker laughed back. This time, the whole delegation laughed, and the loudspeaker duly roared with laughter. Next time, there was so much laughter from the loudspeaker that the microphone picked it up, and so made the loudspeaker laugh again. The air around Farnborough resounded with the laughter from this self-amusing system.

Now that demonstration showed that the argument about not being able to generate centimetric waves was false—for here we had a system which was capable of generating laughs at rates much higher than once in three seconds (the transit time of the sound) and could indeed generate sounds with periods of less than one thousandth of a second. What mattered was not the duration of the transit time, but its constancy, so that sounds did not get

blurred in the transit. I actually used this analogy to persuade the Admiralty that centimetric wave generation should be possible; and the fact that the Clarendon Laboratory was asked to work on this problem in 1939 was in part due to this event.

Another piece of false doctrine at about the same time was that it was impossible to make a bullet-proof fuel tank. Our bombers in the early raids on Kiel proved very vulnerable because a single shot through a fuel tank would stop them returning across the North Sea. By contrast, German aircraft proved difficult to shoot down—they went on flying despite several shots through the tanks. When we ultimately shot one down near the Firth of Forth, we saw that it had self-sealing tanks. The subsequent enquiry into our failure to fit similar tanks revealed a cautionary tale. It turned out that there were ideas about bullet-proof self-sealing tanks before the end of the First World War. In peace, of course, the ability to resist bullets was of little advantage: what would be an enormous comfort would be a tank that would not rupture in the event of a crash. The specification was therefore amended, to call for a tank which was both bullet-proof and crash-proof. Between the Wars, various inventors produced tanks, including some very like those ultimately used by the Germans. But each tank was duly taken to Farnborough, filled with fuel, and heaved over the side of a building, so that it fell some 60 ft. on to concrete. All the tanks burst, and so the doctrine grew up that fancy tanks were no good; we thus entered the Second World War without bullet-proof tanks because we could not make a crash-proof tank. Once again trouble had arisen through applying a criterion subsidiary to the operational problem.

The history of bombing in the Second World War illustrates how doctrine can develop from early disappointments to false postulates of impotence. At the beginning, we deluded ourselves that we could hit small targets in Germany; and in this phase we aimed at some crucial targets such as oil-production plants. This effort failed, and it became a doctrine of impotence that we could not expect to knock Germany out by attacks on what were called 'panacea' targets; such targets were held to be false concepts. The real reason for the failure was not the concept but the inaccuracy of our bombing, which was only good enough for hitting area targets such as towns. This therefore became our policy. In the meantime, our bombing accuracy sharply improved—but only in the last few months of the War was it switched back to oil targets. It then proved strikingly effective; but it could probably have been similarly effective several months earlier if it had not been inhibited by the doctrine of the impossibility of knocking out oil that had sprung from our previous disappointment.

Almost all the foregoing examples have this in common. Someone tried to do something and failed. He then invented a false reason for his failure, and this was usually a postulate of impotence when it should have been an admission of incompetence; but it was enough to obscure the true possibilities for some years, and to discourage others from making the attempt.

When I was an undergraduate it was still being debated whether a steam locomotive could be built to run at more than 100 m.p.h. The famous *City of Truro* had once been reported, shortly after 1900, at rather more than 100 m.p.h. downhill, but in the nineteen-twenties this figure could not be equalled in deliberate efforts with more powerful engines, even when streamlined. One cause of failure, Sir William Stanier told me, was that engineers had forgotten to allow for the expansion of steam in the super-heater tubes, which ought to have been made with gradually widening bores to keep down the steam velocities at the exit end, and thus reduce the superheater resistance. When this measure was taken, along with others, speeds easily went beyond the 100 m.p.h. figure; and those of us concerned with elementary physics have for a century

taught that because of linear expansion it is necessary to have frequent gaps in the rails; Kelvin calculated that at least two hundred yards of gaps were needed between London and Edinburgh. We have now to explain why, contrary to this doctrine, we are using great lengths of long-welded rail. The answer is that, if care is taken, the expansion forces, although great, need not be dangerous: these forces—which are along the length of the rail—can exert only a small component at right angles, and this can be contained by adequately securing the rail to its twin and to the ground.

Lest we laugh at the engineers, let us remember that pure science has had its own follies through refusal to face non-conforming evidence. The French Academy about 1780 denied the possibility of stones falling out of the sky: almost every astronomer and every physicist during 1932–1940 took no notice of Janaký's remarkable discovery of radio waves from the Milky Way: many geologists held for a long time that it was impossible for the continents to move: the very word 'atom' postulates an impotence that has been spectacularly shattered: and the supposed inability of Nature to distinguish between mirror-symmetrical arrangements has apparently been dispelled by the experimental violation of parity.

With such examples, we may wonder whether any of our postulates of impotence accepted to-day will be challenged. Shall we, for example, ever be able to go behind the limitations of electromagnetic quanta as means of observation? How far shall we be able to see into the structures of what we call elementary particles, or into the mysterious processes of life? Niels Bohr<sup>24</sup>, in his *Atomic Physics and Human Knowledge*, has exemplified that same reservation towards living systems that Kelvin and others placed on the second law of thermodynamics. They were careful to point out that they did not know whether this law held for living systems; and Bohr (p. 100) has held that "an account, exhaustive in the sense of quantum physics, of all the continually exchanged atoms in the organism not only is not feasible but would obviously require observational conditions incompatible with the display of life". But it will be interesting to see how far we can go.

Where, then, do we stand after this ramble through theory, experiment, and technology, and through genuine and false impotence? We have seen the philosophical fascination of arguing from impotence: each postulate describes a boundary condition for human achievement

and understanding. The assembly of postulates provides a framework of external anchor-points inside which the whole of physical knowledge can be fitted and 'explained'. But good postulates are not to be cheaply won, and, like good anchors, they must be well tested before employment. The price of the test is often a hard experimental beating against the bounds of experience, and a penetrating theoretical search for an explanation of the experimental failure in terms of what is already known. Only when theory and experiment have jointly and exhaustively failed can we be reasonably justified in trusting a new principle of impotence. Otherwise, we shall invent false reasons to delude ourselves away from achievements that could be within our competence. Principles of impotence, like other hypotheses, are not to be multiplied without necessity.

## RESEARCH IN INDUSTRY IN INDIA

By S. H. M. HUSAINI, A. GHOSAL and A. RAHMAN

Survey and Planning of Scientific Research Unit, Council of Scientific and Industrial Research, New Delhi

A SURVEY of research as carried out in industrial establishments in India has been made by the Survey and Planning of Scientific Research Unit of the Council of Scientific and Industrial Research. The interest of business and industrial establishments in scientific research is of recent origin; even two decades ago they were sceptical of the utility of research in augmenting production. The survey was directed towards estimating research efforts made by the industrial establishments and also towards assessing the contribution of research towards growth of production. It was intended primarily to have a quantitative analysis of the situation so far as possible. A country-wide survey of all the establishments was planned; but it was found that only bigger establishments maintained research departments and others primarily made use of research results.

It was, therefore, decided to make a detailed study of research efforts in twenty-five top industrial establishments over the period 1955–62; the main observations of the survey of these establishments have been incorporated in this article. Out of the twenty-five establishments, four were in the public sector, and twenty-one in the private sector. A little more than half these establishments are engaged in the production of chemicals and pharmaceuticals products, whereas the other half included firms manufacturing rayon, textiles, iron and steel and electrical machinery and metallurgical products. Two of the big firms engaged in the manufacture of chemicals were subsidiaries of their parent companies in Britain, whereas one foreign firm collaborated with the Government of India in manufacturing products. Out of two steel plants considered, one was in the public sector and the other in the

private sector. All these establishments had fully equipped research departments.

### Personnel

Detailed statistics of personnel employed in these establishments were available. For all the twenty-five establishments together, production, maintenance and sales accounted for about 60 per cent of the total staff strength, administration about 18 per cent, routine technical and auxiliary jobs about 17 per cent and research and development for only 5 per cent of the total.

There was, however, variation from industry to industry. Those producing chemicals (including paint and varnishes), dyestuffs, insecticides, and rayons employed relatively more research staff than other industries. It was interesting to find that very few research personnel were employed by pharmaceutical industries covered in the survey. One metallurgical firm in the survey employed as much as 63 per cent of its total staff in research and development (for this firm, research is an adjunct for production).

The personnel employed only in research and development departments have been analysed under three headings: (a) scientists and technologists; (b) auxiliary technical staff; (c) administrative and other staff. The growth of personnel under all these heads has been considerable during the period 1956-62. It was found that in all the twenty-five establishments together the staff strength in research and development departments increased seven-fold during the period 1956-62; out of them the number of research personnel (scientists and technologists) increased seven-fold; the auxiliary technical staff increased about eight-fold. The growth was greatest during 1956-60. During the period 1960-62 the increase in the strength of research personnel attained 25 per cent. These norms, however, vary from industry to industry. A few characteristics for particular industries were observed regarding the distribution of personnel in research and development departments. In 1962 in drug and pharmaceutical establishments, for every two scientists one supporting staff was employed; in two steel plants, for every three scientists two supporting staff were employed; in insecticides, for every two scientists one supporting staff was employed; and for chemical industries, for every three scientists there was only one supporting staff.

An analysis of personnel by fields of specialization was also made for the years 1956-61. It was found that in the pharmaceutical establishments covered most scientifically qualified personnel were science graduates who did not specialize in any particular branch of science; these were employed mainly in production and maintenance departments. Steel plants included in the survey have started recruiting more science graduates not specializing in any particular discipline since 1961, primarily due to the fact that they did not get specialized engineers and technicians at the moment they required them; they planned to train these young graduates for various specialized jobs. Among the specialists, chemists exceed others in numbers; chemists were employed in large numbers particularly in a rayon factory, chemical factories and dyestuffs factories. The chemical engineers are also increasing in numbers in the industries, especially in steel plants, chemical and paint factories. Mathematicians, physicists and statisticians are conspicuous by their absence in most of the industrial establishments. In 1962, however, a large number of physicists were recruited in steel plants.

Analysing the distribution of scientists and technologists in various departments of all the industrial establishments covered, we found that about 35 per cent were employed in production, 14 per cent in maintenance, about 7 per cent in sales, 10 per cent in quality control and routine technical jobs, and 11 per cent in research and

development. The distribution, however, varies from industry to industry. Examining the age distribution of the scientific personnel in industries, we found that in rayon, lignite and metallurgy establishments covered in the survey more than 70 per cent were less than thirty, whereas in drugs, pharmaceuticals, dyes and dyestuffs and electrical machinery only 10-17 per cent were less than that age. In electrical machinery a little less than 60 per cent of all scientists and technologists were in the age-group 30-40.

A study of movement of scientific personnel to and from research and development departments has been made over the period 1958-63. Four types of changes were considered; transfer on promotion to other departments, transfer without promotion to other departments, resignations from the establishment and death or illness. It was found that most of the exits were due to transfer on promotion to other departments within the establishment, though during the period 1960-63 a number of transfers to other departments were effected without any promotion. Resignations from the establishments were comparatively small.

### Research Expenditure

An analysis of expenditure in the firms surveyed has been made. A few firms were hesitant in giving the details of their expenditure; others, however, gave the expenditure figures in great detail. The significant observation made from the survey was the small amount of expenditure by the industrial establishments on research and development. One pharmaceutical establishment spent only 1.5 per cent of a total recurring expenditure of Rs. 105 millions on research and development during 1958-62; four enterprises in chemical industry together spent only 0.8 per cent of their total expenditure of Rs. 224 millions; in two steel plants together, out of a total recurring expenditure of Rs. 1,472 millions over the same period, a little less than 0.1 per cent was spent on research and development. Comparatively high proportionate expenditure on research and development was observed in an insecticide establishment (about 5 per cent of the total).

It was originally intended to relate research expenditure to the value added (or to the value of net sales) in the establishments studied. The figures obtained so far are only approximate, though a few firms have also given detailed figures for these. A detailed investigation of the ratio of research expenditure to net sales (or valued added) is to be made; efforts are also being made to examine the elasticity of net sales with respect to research expenditure or vice versa. From rough analysis it is found that the rate of increase in the research expenditure is in many cases greater than the rate of increase in the total expenditure; but since the total research expenditure is on a very low level it appears that adequate research is hampered in the industry.

### Utilization of Research

Even though research efforts are not substantial in most of the industrial establishments surveyed, it is encouraging to find that most of the establishments exploited the processes which were developed internally. Four chemical firms adopted more than 80 per cent of the processes developed internally, whereas the rest were brought from outside sources; in the dyestuff establishment all the fifty-one processes exploited during 1958-62 were developed internally. This points to the fact that research in the field of applied chemistry and dyes has a fairly high standing in India, so that the respective firms can afford to compete in the market by developing their processes. The same conclusion holds good for the new designs used during 1958-62 by the chemical firms. It should, however, be borne in mind that the conditions regarding research and development prevailing in the big industries covered

in the survey do not hold true for numerous smaller establishments, most of which do not have their own research laboratories but depend on buying processes either from abroad or from other sources. The detailed investigation of all industries, which has been taken up by the Unit, will lead to important conclusions which will be representative for India at large.

### Contributions

The contributions by research departments of industrial establishments in terms of research papers, patents and inventions have also been examined. Most of the research papers were published by the research departments of drug and pharmaceutical and chemical firms. The research department of one steel plant also published a number of research papers during the period 1955-62. During the same period the number of research papers and technical reports published by the active departments of the establishments examined increased from 41 to 313. It is, however, generally observed that very few contributions to basic research were made by the research departments. It is expected that in the near future managers will become more research-conscious and more scientists will carry out basic research along with the problems of direct interest to the firms concerned.

From the nature of the papers published by research departments we find that very little engineering research was performed in the firms during the period 1955-62.

### Other Aspects

From the investigation carried out during the period 1955-62 it was found that development in the industries surveyed was, to a great extent, due to foreign collaboration both in terms of employment of foreign experts and also of the equipment. In four chemical firms 82 per cent of the money invested by the foreign collaborators was for purchase of specialized equipment; this percentage was 71 for the electrical industry; in the insecticides factory almost all the money invested by foreign collaborators was for employing consultants.

Fourteen industries are actively collaborating with the national laboratories by way of referring their problems including developmental programmes.

It is gratifying to find that the big establishments have started to train qualified scientists within the industry so that in future they become motivated towards research for solving the problems of the firms concerned. Ten firms out of twenty-five covered in the survey are primarily acquiring technical knowledge from foreign countries (two through their parent companies abroad).

## UNIVERSITY OF NEWCASTLE UPON TYNE

### MERZ COURT

By PROF. J. M. COULSON

Department of Chemical Engineering, University of Newcastle upon Tyne

THIS is the age of university expansion, and the University of Newcastle, in common with other universities, has steadily expanded its facilities and is not only the largest university centre in the north of England but is also noticeably a key centre of technological activities. Although sited within the city boundaries, it is fortunate in being adjacent to the exceptionally large Town Moor, covering one thousand acres, which gives it a very pleasing aspect on the northern side.

The latest and largest addition to the buildings is Merz Court, which was officially opened by the Prime Minister on May 7 and which provides accommodation for Chemical and Electrical Engineering, and also for the Department of Mathematics (Fig. 1). The north-eastern region has a long history as one of the key areas of engineering, including electrical engineering, and there are also very substantial chemical installations in the region. It is therefore appropriate that the new building should reflect the industrial achievements of the area by being named after the Merz family, who indeed played a notable part in the development of both electrical and chemical activities.

Dr. Theodore Merz came from Germany to enter the chemical industry, first in Glasgow and then in Newcastle. He is perhaps best known for his activity in the founding of the North Eastern Electricity Supply Company, which has since merged into the North Eastern Electricity Board. He has, in addition, a permanent place in the history of the University as one of those responsible for the foundation of the Durham College of Science which later became a part of the present University. His book on the *History of Thought in the Nineteenth Century* gives him a permanent place with the thinkers of his time. His son, Charles Merz, born in Gateshead, was trained as an electrical engineer, and later founded with William McLellan the internationally known company of Merz and McLellan, who have been associated particularly with electric power installations over a long period of

years. His second son, Norbert Merz, played an important part in the development of the north-eastern region and contributed in particular to the North Eastern Electricity Supply Co., Messrs. Reyrolle, Ltd., and Thermal Syndicate, Ltd.

Merz Court provides a usable floor area of 114,000 sq. ft. on a site area of only 47,000 sq. ft. This is broadly divided so that Chemical Engineering has 30,000 sq. ft., Electrical Engineering 50,000 sq. ft. and Mathematics 20,000 sq. ft., with the remainder for general purposes. To provide this large building on so small a site presented a major problem to the architects, not only because the Engineering Departments required large laboratories, many of which must be on the ground floor, but also because the soil required strengthening in order to support the heavy loads of such a building. The building is formed round a quadrilateral base with a central courtyard. In general there are six storeys, but some of the laboratories spread through two floors. The west side houses the Electrical Engineering Department on all floors, while on the east the Chemical Engineering Department occupies the lower three floors with Mathematics on the upper floors. The south side provides a group of lecture rooms available to all departments with a top floor again for the use of the Mathematics Department. The much shorter north side contains the workshops of the Engineering Departments, a students' common room, a seminar library for the building, and some small offices.

The construction of the building is of reinforced concrete and the east and west wings are each of 60 ft. in width, providing, in the case of Electrical Engineering, very large laboratories. The south side includes the largest lecture theatre, which will accommodate about two hundred students and which is well fitted for sound amplification and projection units. There are two preparation rooms which serve the other lecture rooms in this section. This south front is supported on a single span of 111 ft. over the entrance to the inner courtyard.

Fig. 1. Mers Court, University of Newcastle upon Tyne

Such an arrangement provides an open access on the ground-level and breaks up what would otherwise be a rather heavy front to this side of the building. The front is further relieved by an unusual bridge pathway which provides communication between the other engineering buildings and the main University Library.

The internal wall finishes are fair-faced concrete and fair-faced brick in the laboratories, and plastered concrete in the lecture and administrative rooms. Wood-block and cork-tile floors have been widely used except in some Chemical Engineering laboratories, where tiled floors, resistant to acid and solvents, have been laid. The door frames and much of the joinery is from the hard paduak wood and many of the flush doors are finished in the new polyurethane paint. The arrangement of the ceilings is interesting in that the use of softwood slats spaced very slightly apart and backed with fibre-glass gives sound insulation at an economical cost. The corridors, which have been kept to a minimum in the general design, have softwood open slatted ceilings which have been suspended where necessary. These slats can easily be removed to provide access to the surface ducts—a very important requirement in an engineering building.

The building is heated from an oil-fired installation in the basement, giving a total output of 34 million B.Th.U./h. This plant supplies most of the building with low-pressure hot water pumped through finned tube convectors.

Control is provided by fans operating from thermostats, such an arrangement giving fairly speedy heating-up when required. Special time-switches enable the heating load to be modified for night operation. The boiler plant also supplies steam for experimental purposes to the Chemical Engineering Department at a pressure of 100 lb./in.<sup>2</sup> and a separate electrode steam boiler provides steam at 500 lb./in.<sup>2</sup> to one laboratory.

#### Laboratory Supplies and Equipment

The supplies of electricity to both the Electrical and the Chemical Engineering Departments are extensive and complex. Two 750-kVA transformers mounted in the basement of the Electrical Department provide the main source of power; other equipment generating the various forms of supply is also mounted in the basement. The supplies to the five floors of the Electrical Department are taken through coded cables in large ducts with ample spare capacity. These cables feed either directly to central distribution boards or to small laboratory panels. Three 3-phase and neutral a.c. supplies are distributed from the basement. These are 415 V at 600 amp, 240 V at 200 amp, both of 50 c/s, and for servo work 60 V at 200 amp, and a further supply at 500 c/s. Six mercury arc rectifiers provide 120–0–120 V at 1,000 amp d.c., and in addition a large lead acid battery provides 120–0–120 V

d.c. There are also available two motor generator sets giving 100 amp at 240 V. In these laboratories, special panels designed in the Department are used. These panels, which may be regarded as engraved line diagrams, provide sufficient information for students to understand the arrangements for supply and when necessary modify connexions relatively easily. The various connexions throughout the Electrical Department enable pieces of equipment to be connected electrically from one laboratory to the other without much difficulty. This flexibility is regarded as a considerable asset.

In the Chemical Engineering Department the supplies of electric power are much simpler but are substantial in quantity. The general scheme is to arrange bus-bars either at one level or, in the case of the pilot plant laboratory, at two levels. Tappings from these bus-bars can readily be obtained at any desired position, but a number are fitted in for initial operation.

The Chemical Engineering Laboratories are also provided with compressed air, gas, water, and in many cases steam at 100 lb./in.<sup>2</sup>. There are no general facilities either for vacuum or for hot water, but these can be provided when required for individual pieces of equipment.

### Research and Teaching

Both the Engineering Departments have some special laboratories for research purposes, but in many cases, particularly in the Chemistry Section, the research and undergraduate teaching are combined so far as possible. Some special facilities in the Electrical Area include a screened room and a high-voltage laboratory. They are also provided with equipment for developing analogue computers and electronic circuitry. On the heavy current side, work is mainly on speed control of motors.

In Chemical Engineering the research activities are broadly related to the new field of electro-chemical engineering, for which there is a large special laboratory, to com-

bustion research, reactor design, and to the field of high-intensity heat transfer. Again, both Engineering Departments have their own workshops covering machine work, electronic work, instrument work and glass technology.

The top floor, mainly devoted to the Department of Mathematics, gives an added sense of lightness as a result of the fitting of a number of glass domes on the flat roof. In this section, the architects have successfully provided a little more perambulatory space, some of which is available on two terraces outside the normal rooms. The greatly enlarged premises for Mathematics are a source of considerable pleasure since this Department has managed to grow rapidly to one of those providing a significant contribution to the training in this key discipline. They have active research work in hand in functional analysis, group theory, mathematical logic, potential theory, continuum mechanics, fluid dynamics, relativity and mathematical statistics.

To the visitor and to those who work in it, there is no doubt that this building represents a step forward in the general style for the University. The large area of walls finished in white with rather light ceilings gives an air of space which is much appreciated. The wide variation in heights of room and the interesting development of the common-user lecture block facing south all help to excite the visitor and give the permanent dweller satisfaction. To have fitted three such different departments into the same block and woven them to form a united home is an undoubted achievement, and those who work there will be indebted to the architects, Messrs. Richard Sheppard, Robson and Partners. Each of the departments has a strong postgraduate research school, and Merz Court can be looked on as one of the major centres of new development in the north-east.

In the course of his tour round the building, the Prime Minister pointed out the general importance of modern technologies and the need for each part of the country to play its individual part in a successful community.

## OBITUARY

### Prof. John E. Driver

PROF. JOHN E. DRIVER, who died in Winchester on March 27, was the youngest son of Frederick and Mary Eleanor Driver, and was born in Montserrat in the West Indies on October 26, 1900. He left Montserrat at the age of ten and continued his education at West Buckland School in Devon and High Pavement School in Nottingham, from which he won a scholarship to what was then University College, Nottingham. He was remarkably advanced for his age, and as a student during the First World War, doing part-time training in the Officers Training Corps, read for an honours degree in chemistry under Prof. F. S. Kipping, and graduated at the early age of nineteen. The commanding officer of the Officers Training Corps, Major S. R. Trotman, was city analyst and part-time lecturer in applied chemistry, and Prof. Kipping also assisted the Corps as musketry instructor, so that there was close integration of his academic and military studies. This occurred in another form in his service during the Second World War.\*

Driver was appointed to the staff of University College, Nottingham, in 1920 and remained there until 1938 when he left to take up a similar post at Cambridge, which he held until the end of 1945, though absent on war service for much of the time. Although conditions for research at Nottingham in the pre-war years were difficult and formal teaching duties very heavy, he began research which continued throughout his career, making important contributions to such topics as the chemistry of crude drugs, dyes of the aurin type, the Fries re-arrangement, and

phenol aldehyde reactions, publishing mainly in the *Journal of the Chemical Society*. He was a lucid and inspiring teacher to pharmacy as well as chemistry students and was popular with staff and students alike. For some years he was an examiner of the Pharmaceutical Society of Great Britain. He showed a flair for authorship too, especially in the field of pharmaceutical chemistry and the chemistry of crude drugs. In collaboration with A. O. Bentley he published the *Textbook of Pharmaceutical Chemistry* in 1925, and was largely responsible for the revision of this book in the several new editions produced in the subsequent 40 years. He also published, with G. E. Trease, *The Chemistry of Crude Drugs*. His other books were *Bakery Science* and *Tables of Qualitative Analysis*, and he was checking the proofs of the seventh edition of the popular *Analysis* book at the time of his death. His career at Cambridge had scarcely begun when it was interrupted by the Second World War. His qualifications and experience led him naturally in the Services into the Chemical Warfare Branch of the Royal Engineers. His service in the Army during 1940-45 included a period of two years at the School of Chemical Warfare at Winterbourne Gunner as brigade major, as well as periods with the 21st Army Group and the War Office.

Driver became the editor of the *Journal of the Chemical Society* in 1946, filling this office very effectively until 1949 when he accepted the invitation to become professor of chemistry in the University of Hong Kong. He took up his appointment on April 11, 1949, and filled it with distinction until an intermittent but serious illness forced him to retire on March 11, 1960. The Faculty of Science

in the University of Hong Kong had been formed only just before the Second World War, though chemistry, physics and mathematics had been taught earlier within the Faculty of Arts. The newly created Faculty had its first meeting on July 4, 1939. Development was interrupted in December 1941 by the invasion of Hong Kong, when the University was forced to close. It did not re-open until 1946 and had to start again almost from scratch. In this vital phase of re-establishment and expansion he played an important part. He planned a new chemistry building, completed in 1953 and described in the *Proceedings of the Chemical Society* in 1958, which has proved one of the University's finest buildings. He was able also to resume his research activities. Perhaps his main contributions were nevertheless in the exercise of his flair for clear thinking, clear presentation of views, and as an administrator. He was elected dean of the Faculty of Science in November 1950 and held office continually until November 1959. His talents as an author were particularly helpful in his duties as chairman of the Board of the University of

Hong Kong Press. His valuable services were, however, by no means confined within the University. He acted several times as external examiner in the University of Malaya. He took also a great interest in extra-mural affairs. He served as a Justice of the Peace. He served also on the Hong Kong Government Pharmacy Board and Dangerous Goods Committee. He was a Fellow of St. John's College in the University and a member of the Council of St. John's Cathedral in Hong Kong. His notable contributions to all aspects of University life led the Senate to confer on him the title of emeritus professor on his retirement.

Despite poor health, retirement did not end his professional career entirely. He continued to revise his books, and the University of Hong Kong was very glad to have his continued service as its representative in the United Kingdom. He retired to Hampshire, where country life and the devoted care of his wife brought back a measure of health and the ability to sustain his professional and other interests.

J. MILLER

## NEWS and VIEWS

### Director-General of the Meteorological Office:

Sir Graham Sutton, F.R.S.

SIR GRAHAM SUTTON, who will be retiring from his position as director-general of the Meteorological Office on September 30, was appointed head of the Office in 1953 after unusually varied experience in Government Science: superintendent of research at the Chemical Defence Experimental Establishment, Porton; superintendent, Tank Armament Research; chief superintendent, Radar Research and Development Establishment, Malvern; and latterly as Bashforth professor of mathematical physics and dean of the Royal Military College of Science. His personal scientific reputation rested on his pioneer researches in diffusion and other problems of the Earth's atmospheric boundary layer, consolidated by his textbook *Micrometeorology*, which appeared first in 1953 and has become the standard text. Under his direction the Meteorological Office has undergone numerous changes towards meeting its primary task of providing a national meteorological service, its hitherto dispersed headquarters have been unified at its new and impressive scientific and administrative centre at Bracknell, Berkshire, and Weather Centres, open to the public, have appeared in a number of cities; but perhaps the large development of the research side of the Office, to the status of a directorate employing some sixty research scientists with high-speed computers and other modern facilities to match, will come to be regarded as his most far-reaching innovation. He leaves the Meteorological Office as a well-founded, up-to-date, scientific institution. Fortunately, in his new post as first chairman of the Natural Environment Research Council (*Nature*, 205, 748; 206, 873; 1965) his wide experience and proved ability will continue to be devoted to the benefit of science for some time to come.

Prof. B. J. Mason, professor of cloud physics in the Imperial College of Science and Technology (*Nature*, 188, 781; 1960), has been appointed to succeed Sir Graham Sutton as director-general of the Meteorological Office.

### Controller in the Ministry of Technology:

Dr. J. B. Adams, C.M.G., F.R.S.

THE Minister of Technology, the Right Hon. Frank Cousins, has appointed Dr. J. B. Adams, director of the Culham Laboratory of the U.K. Atomic Energy Authority, to be controller in the Ministry of Technology. In addition

to his duties with the Ministry, Dr. Adams will continue to direct the work of the Culham Laboratory.

John Bertram Adams, who is forty-five years of age, entered Siemens Research Laboratory from Eltham College. He was employed between 1940 and 1945 in the Telecommunications Research Establishment, Malvern, and afterwards in the Atomic Energy Research Establishment, Harwell. During 1953-61 he served with the European Organization for Nuclear Research (CERN) at Geneva, for the last fifteen months as director-general. As director of the Proton Synchrotron Division, he was responsible for the design and installation of the highly successful 28-GeV proton synchrotron which is the major equipment of the laboratory. In 1961 he rejoined the U.K. Atomic Energy Authority as director of the newly established Culham Laboratory. Dr. Adams was made a Companion of the Order of St. Michael and St. George in 1962. He was awarded the honorary degree of D.Sc. by the University of Geneva in 1960 and by the University of Birmingham in 1961. Dr. Adams was elected a Fellow of the Royal Society in 1963.

### Mathematics in the Imperial College of Science and Technology: Prof. G. E. H. Reuter

PROF. G. E. H. REUTER has been appointed professor of mathematics in the Imperial College of Science and Technology from October 1965. For the past six years he has been professor of pure mathematics at the University of Durham. Educated at Trinity College, Cambridge, he took up his first appointment, in the Scientific Civil Service, in 1941. In 1946 he moved to the University of Manchester where he was made senior lecturer in 1955. His research has been chiefly concerned with the analytic theory of Markov chains. The development of a population of any kind may be viewed as a random process and a Markov chain may be thought of as a far-reaching generalization of such a process. While Prof. Reuter has, for example, made a study of competition between insect populations, his most important work concerns the theory of general Markov chains. In the case of populations, one assumes known the birth and death rates at the possible population sizes and attempts to deduce various aspects of the population behaviour from these. To solve the analogous problems in general is perhaps the main aim of Markov chain theory. Prof. Reuter has shown that operator theory is a natural tool for tackling

many of these problems and that it may be applied to solve some of them under wide conditions. One might single out his work on the Kolmogorov equations and his work with Dr. D. G. Kendall (now professor of mathematical statistics at Cambridge) on ergodic theory and on 'pathological' Markov chains.

#### Pure Mathematics in the University of Durham

FOLLOWING the appointment of Prof. G. E. H. Reuter to a professorship in mathematics in the Imperial College of Science and Technology, two professorships have been established in pure mathematics in the University of Durham. Dr. T. J. Willmore and Dr. C. Hooley have been appointed to these chairs.

#### Prof. T. J. Willmore

Dr. Willmore was educated at Palmer's School, Grays, and King's College, London, where in 1939 he gained a B.Sc. degree with first-class honours in mathematics. He was appointed an assistant in the Mathematics Department at King's College, but the outbreak of the Second World War changed his plans and from 1939 until 1946 he was on the scientific staff of the Royal Air Force at Cardington. After the War, preferring a university career to the Scientific Civil Service, he resigned his appointment and in 1946 became a lecturer in mathematics at Durham. In 1954 he was appointed lecturer in the Department of Pure Mathematics at Liverpool, and became a senior lecturer in 1956 and a reader in 1962. Dr. Willmore's early research was on elasticity and relativity theory, but he soon became interested in differential geometry and most of his work has been in this field. He has published many papers on harmonic spaces, parallel distributions and derivations on manifolds, and has more recently become interested in global problems, particularly those related to curvature. He is the author of *An Introduction to Differential Geometry*, which is now a standard undergraduate and postgraduate text in Britain and the United States. He also collaborated with H. S. Ruse and A. G. Walker in the production of a monograph on harmonic spaces and with I. R. Porteous in an undergraduate text on topological geometry which is soon to be published. The training of mathematics teachers is a particular interest of Dr. Willmore's and he has for some time actively assisted the Institute of Education and the Extra-Mural Department in Liverpool, where he helped to organize and run courses designed to bring teachers up to date in modern mathematics. It is always a compliment to be appointed as a senior member of a university where one was formerly a junior, and Dr. Willmore's distinction as a geometer and a teacher, together with his energy and wide interests, will contribute much to his former university and its Mathematics Department. Dr. Willmore takes up his new appointment on October 1.

#### Dr. C. Hooley

Dr. Hooley was educated at Abbotsholme School, Derbyshire, and (after two years national service) at Corpus Christi College, Cambridge. He was a Fellow of the College from 1955 until 1958, and since then has been a lecturer in mathematics at the University of Bristol. Dr. Hooley's researches in the analytic theory of numbers have brought him an international reputation among experts in the field. The subject is one which has been deeply investigated during the past fifty years, and the frontier of the knowledge which is attainable by conventional methods is fairly well defined. But it is sometimes possible to make further advances by a combination of analytical and arithmetical reasoning, the latter being technically elementary but usually very difficult. In this way Dr. Hooley has succeeded in proving a number of results that had previously appeared to be out of reach. As an illustration, one may mention his proof (*Math. Zeitschrift*, 69, 259; 1958) that for 'almost all' those

numbers that are representable as  $x^2 + y^2$ , with positive integers  $x, y$ , there is only one such representation.

#### Medical Research Council: Appointment of Head of Division of Physiology and Pharmacology, National Institute for Medical Research

PROF. B. DELISLE BURNS has been appointed to the scientific staff of the Medical Research Council as head of the Division of Physiology and Pharmacology at the National Institute for Medical Research, in succession to Prof. W. S. Feldberg, who will be retiring from this post in November 1965. Prof. Burns, at present professor and chairman of the Department of Physiology, McGill University, Montreal, was a member of the Council's staff at the National Institute from 1946 until 1950. He has been particularly concerned with neurophysiological investigations of the brain, and it is intended that his work in this field should be continued when he takes up his appointment at Mill Hill next year.

#### Computers, Technologists and their Applications

IN a written answer in the House of Commons on June 24, the Minister of Technology, Mr. F. Cousins, gave the names of 17 research associations which actively encouraged the use of computers in their respective industries; of 18 research associations which had access to computers on their premises, at universities or at member firms; of 15 research associations using computers in their routine research (the names of some associations appear on all three lists). In another written answer on June 24, Mr. Cousins stated that of 4,064 non-industrial Civil Servants employed by his Department on June 1, 1965, 1,400 had university degrees or equivalent qualifications in scientific or technological subjects, and about another 1,400 had other scientific or technological qualifications. In a third written answer, Mr. Cousins stated that since the creation of his Department, besides the sponsored study by the Tavistock Institute of Human Relations of factors affecting the status of engineers, and work on behalf of the Committee on Manpower Resources for Science and Technology, action was in hand, in collaboration with other Departments, to promote the greater use of technological subjects in television and radio programmes, and to produce special booklets and films for wide distribution among young people.

#### Oceanographic Research

IN reply to questions regarding oceanographic research and the representation of the Ministry of Defence on the Natural Environment Research Council, in the House of Lords on June 22, the Minister of State for Education and Science, Lord Bowden, said that the Government was quite satisfied in this respect. The membership of the Council included Prof. M. J. Lighthill, Sir Edward Bullard, Prof. J. E. Harris and Dr. C. M. Yonge, all of whom had made important contributions to oceanography or related fields and had served on the National Oceanographic Council. The terms of reference of the Natural Environment Research Council were adequate for it to continue to advance the national effort in scientific oceanography, and this would be assisted by the fact that there would be one source of funds for basic oceanographic research. The Ministry of Defence would have an assessor on the Natural Environment Research Council, and would also be represented on the Council's Committee responsible for oceanography. The Minister was anxious to continue to co-operate, and the Royal Navy's representatives on the Committee were determined that their Service's interest should be pursued as strongly as when the Admiralty administered the National Institute of Oceanography. There must be close co-operation between the Navy and oceanographic research—on which the Navy spent £590,000 in 1964. On priority of oceanographic research, Lord Bowden said that priorities for various

research programmes were to be assessed by the new Research Council, and it was the Government's intention, in the light of the advice it received from the Research Council, to do what it could in oceanographic research. This was not a field in which inadequate resources need limit Britain's participation.

### Business Schools

In reply to questions in the House of Commons on June 24 regarding progress in establishing the new business schools, the Secretary of State for Education and Science, Mr. A. Croxall, stated that both schools had leased temporary premises which were being adapted and equipped, and staff were being recruited. The first full-time course at Manchester would begin next September. In London it was hoped to hold some part-time courses this autumn and full-time courses would start next February. The London School had appointed its director. He was satisfied that liaison between the Schools and the Ministry of Technology and the Government generally would be close and sufficient.

### Liberal Studies in a Technological Education

UNDER the title *Symposium on Liberal Studies* the British Association for Commercial and Industrial Education has collected a series of articles issued in the Association's *Journal* over the past 18 months (Pp. 40. London: British Association for Commercial and Industrial Education, 1964. 10s.). The president of the Association, Sir Willis Jackson, contributes a foreword, and there is an introduction by Sir Eric Ashby, in which he states his reason for regarding the liberal studies programme in the colleges of advanced technology as one of the initially important educational experiments of this century. There is also a select bibliography compiled by Mr. D. R. O. Thomas, characterized by breadth and vision, though, as always, there is room for two opinions as to the merits of including some particular books as against alternatives. In the first of the six articles, Prof. T. Lupton argues the claims of industrial administration to be a liberal undergraduate study. In the second, H. N. Sheldon describes the aims, content and methods of these studies, which are the responsibility of the general or liberal studies departments in colleges of advanced technology and assesses their value as an integral part of the training of undergraduate technologists. In the third, "Teaching Technology—a Liberal Approach", Mr. J. P. Moore describes the present aims and methods in teaching metallurgy at Bitterne College of Technology; Mr. D. J. Isaac's "Concepts and Methods in Science Teaching" examines the attitudes and assumptions of students and teachers at Brunel College and describes the action taken to remedy an unsatisfactory situation. Under the title "Humanities and Technology—a New Discipline", Mr. A. M. Duncan discusses the imperative need for a single system rather than two separate aspects of the same culture. Finally, Sir Lealie Rowan in an article, "Liberal Studies in Technology", examines the need for a change in attitude to training for management.

### British Admiral: A Super Oil Tanker

ON March 17, 1965, *British Admiral*, the first tanker of 100,000 tons deadweight to be built in Europe, was christened and launched by H.M. The Queen at Barrow-in-Furness, at the yard of Vickers-Armstrongs (Shipbuilders), Ltd. This was a great occasion, but there was also another soon to follow. In April 1965 the British Petroleum Tanker Company, the shipping subsidiary of the British Petroleum Company, celebrated its jubilee and to mark both events a recent issue of the *BP Magazine*, that colourful quarterly, is devoted entirely to sea-going oil-tankers and to the history of the British Petroleum Tanker Company in particular (15, Spring 1965. Pp. 32. British Petroleum Co., Ltd., London, E.C.2). "During these 50 years, the

British Petroleum Tanker Company has grown from modest beginnings to become the operator of one of the largest privately owned fleets in the world. The ships themselves have grown in size and complexity and the business of tanker operation, whether from the viewpoint of the man at sea or in the office, has developed to the point where it is at once both an art and a science." The articles in this publication, written by experts, aided by a series of excellent illustrations and diagrams, not only record the achievements of the British Petroleum Tanker Company over the years, but they are also a valuable insight into the evolution of oil-tankers in general; as such, they make commendably instructive reading for all interested in this vital aspect of international oil operations. The contributions are: "From Whaling Brig to Super Tanker", by M. Clémans and R. Ilian; "Those Who Go to Sea" (anon.); "A Tanker is Built", by Commander E. H. W. Platt; "Special Services", by Captain G. A. B. King. There is a special supplement in photogravure illustrating the actual launching of *British Admiral* and inside this folder are representations of some of the original plans used for its construction. From these and some explanatory notes it is learnt that, compared with the *Queen Elizabeth* (overall length 1,031 ft.), *British Admiral* is 917.5 ft.; breadth is 118 ft., and 128 ft., respectively; the tanker's depth to upper deck is 66 ft.; her service speed, loaded, about 15.5 knots. Other details of engines and general layout of this 'big ship', also of the commodore and chief engineer, whose responsibility she will be, complete what is a most worthy tribute to all concerned with her commission.

### The Quekett Microscopical Club

THIS year the Quekett Microscopical Club celebrates the centenary of its foundation on July 7, 1865. The title of the Club commemorates the name of John Thomas Quekett, professor of histology and conservator of the Hunterian Museum at the Royal College of Surgeons of England. A prominent microscopist in his day, a founder member of the Microscopical Society of London (now the Royal Microscopical Society), Fellow of the Royal Society and of the Linnean Society of London, and author of the *Practical Treatise on the Microscope*, Quekett died in 1861 at the early age of forty-six, greatly respected by all who knew him. There were at the time several suggestions current for commemorating his name in some permanent way. As events have proved, no more appropriate memorial to him could have come of this desire than the association of his name with this Club, which has met twice-monthly for the past hundred years, and to-day enjoys a world-wide membership. Appropriately, the Club's president in this centenary year is Prof. George J. Cunningham, who occupies the chair of pathology at the Royal College of Surgeons. The principal event to mark this occasion will be a two-day celebration meeting and exhibition of microscopy, which will be open to visitors. This will be held in the Central Hall, Westminster, S.W.1, during October 8-9. The theme of the meeting will be two-fold: first, to illustrate the founding and history of the Club; and secondly, to present a survey of present-day microscopy and microscopical equipment in science and industry, in addition to its recreational aspects. Demonstrations of films, slides and microprojection will also be staged throughout the two days.

### The Manchester Museum

THE report for the year ending July 31, 1964, recalls that for several years the policy of the Manchester Museum has been to concentrate on the more attractive display of its extensive collections (Pp. 20. Manchester: The Manchester Museum, The University, 1965). To this end, a new Japanese gallery has been arranged and the Cannon Aquarium opened to the public. The latter was removed from the Zoology Department of the University and

includes displays of tropical and cold freshwater fish, amphibians, snakes and lizards and a variety of invertebrates. Another feature of outstanding interest during the year was an exhibition of the Moon. A commercial firm in the town centre has given the use of a shop-window for the display of a small exhibit. This is changed each month and is already proving an attraction.

### The Coryndon Memorial Museum, Nairobi

DURING the year 1963-64 the authorities at the Coryndon Memorial Museum realized that with the importance now given to East Africa in matters concerning the conservation of wild-life, they were becoming the obvious centre of visual education and propaganda in this connexion (report for the period July 1, 1963, to June 30, 1964, of the Coryndon Memorial Museum, and the Coryndon Museum Centre for Prehistory and Palaeontology. Pp. 52. Nairobi: Coryndon Memorial Museum, 1964). Consequently, the Museum has featured to an ever-increasing extent as a notable tourist attraction. The Coryndon Museum Centre for Prehistory and Palaeontology, established in buildings situated within the Museum grounds, has now completed its second full year of operation. Under the honorary director of the Centre, Dr. L. S. B. Leakey, the results achieved have been extremely encouraging, and the necessary finance has been raised to construct a much-needed additional laboratory. Work has continued on extending the exhibition space in the Snake Park, and a large aviary has now been completed.

### Marble of the Cyclades Islands

THE report for 1964 of the Rugby School Natural History Society contains a report by J. C. Broome which won for him a Trevelyan scholarship (Pp. 24+1 plate. Rugby: Rugby School Natural History Society, 1965). He describes a visit to the Cyclades Islands in the Aegean Sea, which are part of an ancient massif, probably of Cambrian age. The rocks underwent considerable metamorphism and marble was formed from the limestone originally present. Orogenesis during Tertiary times established ridges which later became largely submerged, by movements still in progress, to form island chains. In the Cyclades there are two such chains, continuing the lines of Euboea and Attika, respectively. Paros and Naxos lie between them and are made up of older rocks projecting through the more recent. True calcitic marble is found on almost all the islands, and on many it has been quarried. On Tinos there is also a rock which is known commercially as a 'marble', but which is, in fact, an opicalcite.

From the beginning of the third millennium B.C. the islands were the home of the Cycladean branch of the Aegean Civilization. During the early bronze age the islanders produced various kinds of marble objects, the most important of which are small human figurines. The earliest specimens are flat, violin-shaped objects, scarcely recognizable as human, but the more advanced figures often show rounding of limbs and indications of facial features. The centre of the civilization was Paros, and most of the figures are in Parian marble. Marble was first quarried in the sixth century B.C. The most important of its early uses was statuary, which at this period was limited to two forms, both common on the Cyclades, the kouros, a nude male figure, and the koure, a draped female figure. Except on Naxos, where there was a flourishing school of sculpture using local marble, the islanders worked in Parian marble, which was held in high esteem throughout the world and rivalled only by a variety from Mount Pentelion, near Athens. The first use of marble in architecture was for roofing tiles. Later, in the Temple of Apollo at Delphi, the façade was of marble (Parian) and finally the whole building, as, for example, in the case of the Parthenon (Pentellic with

Parian roofing). The quarries passed to Imperial Rome in the first century B.C. and many Cycladean varieties were exported in large quantities to Rome for building materials. Parian marble was extensively used for making statues. During the Byzantine period the quarries were abandoned, but in the nineteenth century a move was made to reopen them. The only ones that are economically run to-day are those of Paros, Naxos and Tinos, which Broome discusses.

### Hyperbaric Oxygenation

THE collection of papers presented at a conference held by the New York Academy of Sciences in February 1964 provides a comprehensive and stimulating review of the present status of hyperbaric oxygenation (*Annals of the New York Academy of Sciences*, 117, Article 2: Hyperbaric Oxygenation. By S. Attar and 37 other authors. Pp. 647-890. New York: New York Academy of Sciences, 1965. 7 dollars). Treatment of patients under conditions of high-pressure air or oxygen is often considered to be a new science, so it comes as a surprise to read of experiments starting in 1662 and flourishing in the nineteenth and early twentieth centuries. The clinical aspects of treatment of patients suffering from heart complaints or gas poisoning are discussed at some length, as are the effects of high oxygen partial pressure on micro-organisms and toxins. It was encouraging to note that considerable emphasis was placed on the safety aspects that should be observed. One must always remember that when treating a patient in a large chamber, the medical staff are also subjected to the high-pressure conditions and must observe the correct decompression cycle when returning to normal pressure. For example, if they have been at a pressure of 3 atmospheres absolute for 170 minutes, the time taken to return to normal pressure (1 atmosphere absolute) must not be less than 98.8 minutes. The fire hazards associated with high partial pressures of oxygen are also worthy of note since many pieces of equipment normally used in operating theatres may burn with explosive force under these conditions. The appeal made by one contributor for standardization in terminology is especially worthy of notice. For example, chamber pressures are expressed in pounds per square inch gauge pressure, p.s.i. absolute, atmospheres, depth of water and mm of mercury. This provides an exercise in mental arithmetic, but makes comparisons of various conditions tedious.

### Nutrition Research in Hungary

RESEARCH on nutritional and allied problems is expanding in most countries. A small volume recently published—*Year-book of the Budapest Institute of Nutrition 1963*—clearly shows that Hungary is no exception (Pp. xiv+86. Budapest: Institute of Nutrition, 1964). This publication reflects in abbreviated form the varied activity of the Institute. Its staff published seventy communications during the year, and some of them are summarized here. As in some other nutritional research institutes, the coverage extends into fields of food chemistry, microbiology, and also into problems of food and cosmetics toxicology. Among investigations of interest is a series on the factors which influence the composition of human milk. It is shown, for example, that in Hungary the milk tends to contain less vitamin A and vitamin C (in the winter and spring) than in other countries, which is related to a lower intake of these vitamins. On the other hand, a higher allowance of vitamin C is recommended than in the British Medical Association proposals. The effect of fats on protein metabolism is reported. Lard and butter are shown to result in greater excretion of nitrogen than when margarine and sunflower seed oil are ingested; the latter being recommended for normal nutritional benefits and in post-operative diets. Paraffin is demonstrated to interfere with the utilization of carotene but not with its absorption from the intestinal

tract. Other matters reviewed here are a survey of radioactivity in foods, nutritional values of wheat and cabbage proteins, and the use of thin-layer chromatography for lipid examination. An interesting section contains a number of papers on the effects of high-frequency and infra-red cooking (evidently in increasing use in Hungary) on the physical properties of foods and their nutritional losses.

#### Quaternary Diatom Flora in West Sweden

*Diatom Floras in the Quaternary of the Göta River Valley (Western Sweden)*, by Dr. Urve Miller, describes the diatom succession in the silts in the Göta River from Glacial times onwards (*Sveriges Geologiska Undersökning. Series Cc, No. 44*. Pp. 67+6 plates. Stockholm, 1964. 30 kr.). The silts contain a few marine fossils, which prove that they were deposited in an estuary, but at most levels the vast majority of the diatoms are freshwater planktonic species, mainly no doubt carried down by the river, but in part perhaps living in fresh water floating on the top of the sea-water. The succession, which shows some well-distinguished phases, is interpreted as the result of both changing climate and changing freshwater supply. Carbon dating is used. The changes are recorded in the ways used for pollen analysis—a fairly large number is counted (here the number chosen was 2,000) and the percentages of the different species or larger groups are recorded. A good many rare species are noted and figured.

#### The Royal College of Surgeons of England

THE annual report of the Council of the Royal College of Surgeons of England for the year ending July 31, 1964, which includes the report of the Institute of Basic Medical Sciences, contains scientific reports from the Departments of Anatomy, Pathology, Physiology, Pharmacology, Dental Science and Biochemistry, Ophthalmology and Anaesthetics, and the research establishment at Buckton Browne Farm (Pp. 124. London: Royal College of Surgeons of England, 1965). The departmental reports include summaries of research progress, and lists of publications during the year are appended.

#### The Leopoldina German Academy of Sciences: Elections

THE Deutsche Akademie der Naturforscher Leopoldina, Halle, recently elected the following new members in the sections indicated: *Astronomy*, Prof. M. G. J. Minnaert (Utrecht). *Pharmacology*, Prof. F. Markwardt (Erfurt). *Pathology*, Prof. W. Doerr (Heidelberg). *Internal Medicine*, Prof. A. E. Sundermann (Erfurt). *Oto-, Rhino-, Laryngology*, Prof. Rosemarie Albrecht (Jena); Prof. H. Jakobi (Halle); Prof. H. Naumann (Berlin); Prof. H. F. Schuknecht (Boston). *Dermatology*, Prof. H. Kleime-Natrop (Dresden). *Stomatology*, Prof. R. Ritter (Heidelberg).

#### John F. Kennedy Memorial Fellowships at the Weizmann Institute of Science

UNDER the John F. Kennedy Memorial Fellowships Scheme, established by the Weizmann Institute of Science, Dr. Sidney Borowitz, chairman of the Department of Physics of New York University, New York City, and Dr. Henry Wallman, professor of applied electronics of Chalmers University, Goteborg, have been awarded one-year fellowships at the Weizmann Institute of Science for the academic year 1965-66, and Dr. John Blatt, professor of applied mathematics at the University of New South Wales, has been named a visiting professor at the Institute for a one-year period. Two scholarships at the Feinberg Graduate School of the Weizmann Institute were awarded to Y. Frishman, for research in nuclear physics, and to M. Lahav, for research in X-ray crystallography. Two additional scholarships will shortly be announced.

The John F. Kennedy Memorial Foundation, the funds of which have enabled the awards to be made, was established by the Weizmann Institute of Science in 1964; it is intended as a 5-million dollar endowment fund to advance scientific research. Half the fund has already been raised, in the sum of £6.5 million, including £1 million from the Israeli Government, £2 million from American contributors, £3 million from the Weizmann Institute's Endowment Fund, £800,000 from Israel donors. The first recipients were chosen by an international scientific committee consisting of Lord Rothschild (University of Cambridge), Prof. A. Lwoff (Pasteur Institute of the University of Paris), Dr. I. I. Rabi (Columbia University) and Dr. J. Robert Oppenheimer (recently retired director of the Institute for Advanced Study, Princeton).

#### University News:

##### Birmingham

THE following appointments have been announced: *Lectureships*, Mr. G. R. Isaak (Physics); Mr. Y. W. Lam (electronic and electrical engineering); Dr. D. R. Lloyd (chemistry); Dr. N. Crawford (physiological chemistry); Dr. D. G. Gwyn and Dr. D. B. Thomas (anatomy). *Research Fellowships*, Mr. M. M. Bibby (chemistry); Mr. G. S. Boulton (geology); Mr. D. P. S. Peacock (application of scientific techniques to archaeology); Mr. C. S. Repton (electronic and electrical engineering); Mr. J. R. Tittensor (chemistry); Dr. K. Burdett (medical biochemistry and pharmacology).

##### Keele

DR. R. C. MADDISON has been appointed lecturer in physics as from October 1.

##### Nottingham

THE following readers have been appointed: Dr. W. B. Hugo (pharmaceutics); Dr. H. McCallion (mechanical engineering); Dr. R. H. Osborne (geography); Mr. C. Snell (stress analysis); Dr. A. Wright (electrical engineering).

#### Announcements

DR. J. H. QUASTEL, professor of biochemistry at McGill University and director of the McGill-Montreal General Hospital Research Institute, has received the annual award of 500 dollars of the Canadian Society of Microbiologists, in recognition of his many years of outstanding research in microbial physiology and allied fields.

OPEN days will be held at the Mining Research Establishment of the National Coal Board, Isleworth, during July 20-21. Further information can be obtained from C. S. Makower, Mining Research Establishment, Worton Hall, Worton Road, Isleworth, Middlesex.

THE 451st meeting of the Biochemical Society will be held jointly with the Physiological Society in the University of Oxford during July 15-17. Further information can be obtained from the Biochemical Society, 20 Park Crescent, London, W.1.

THE second international conference on "Protozoology" will be held in the Imperial College of Science and Technology during July 29-August 5. Further information can be obtained from Dr. R. S. Bray, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1.

AN international neurochemical conference entitled "Variation in the Chemical Composition of the Nervous System as Determined by Developmental and Genetic Factors", organized under the auspices of the Neurochemical Commission of the World Federation of Neurology, will be held in Oxford during July 25-30. Further information can be obtained from Dr. G. B. Ansell, Department of Experimental Neuropsychopharmacology, the Medical School, Birmingham 15.

## THE MATHEMATICAL ASSOCIATION ANNUAL CONFERENCE

FOR the first time Oxford was the venue of the Mathematical Association's annual conference, the largest ever, which was held during April. Members were accommodated at St. Hugh's (the College of this year's president, Dr. I. W. Busbridge), Somerville, Trinity and Wadham Colleges. They, with large numbers of non-resident members, attended the inaugural meeting in the Sheldonian Theatre and later lectures and meetings in the spacious new buildings of the Oxford College of Technology.

The Association was received on arrival by the Lord Mayor and Lady Mayores at a civic reception, and later by the Vice-Chancellor and Mrs. Wheare at a University reception at Rhodes House. The Association's annual dinner was held in St. Catherine's College. One afternoon was devoted to group visits and tours. Parties visited the University Engineering Laboratory, the *Atlas* computer at Harwell, the Hydraulics Research Establishment, the University Press, and various other places of special interest in and around Oxford. The exhibition of working school computers was a special feature of the main conference. These computers, which were demonstrated by senior pupils from the eight schools exhibiting (Abingdon, Bedford, Exeter, Marlborough, Oundle, Rugby, St. Albans and Sherborne) were, with one exception, made by the schools concerned and included digital and analogue machines, together with some smaller 'games' machines.

The various official reports at the annual business meeting indicated that the Association is in a flourishing condition with many worth-while projects in hand and a membership of now more than 5,000. The Treasurer, however, sounded a clear note of warning that, with increasing costs, the normal rate of increase of membership will be insufficient to provide the necessary finance for all the projects to be completed. He set the Association a target of 7,000 members by its centenary year, 1971. The Schools and Industry Committee has been working on the £3,000 given by the British Petroleum Company, and has good hopes that further assistance will be available to enable it to continue work beyond present horizons. The Association's Diplomas (Teaching and Technology) are now well established and the Teaching Diploma is keeping abreast of modern trends of teaching.

Following the arithmetic, mechanics and statistics reports, the Teaching Committee is now taking a more general look at mathematics as a whole. In particular, the teaching of mathematics between the ages of eleven and sixteen is to receive special attention: an attempt will be made to synthesize the various 'mathematical projects' and form some conclusions. (Meanwhile, the Association is itself publishing a number of papers on selected 'modern' topics, written by individual members: these papers are not intended to represent the Association's considered views in these matters.) The Teaching Committee will also review its primary school and technical college reports, with the view of rewriting them.

Mr. J. T. Combridge, reporting generally on "Current Affairs", spoke of the way in which the Association and the Institute of Mathematics and Its Applications are working closely together to the common good, each in its own field. He saw little danger that the advent of the Institute, which owed much to the Association for its inception and is now well established, would mean any diminution of the Mathematical Association.

The place of the computer in mathematical education is one topic in which the existence of a professional mathematical institution has helped the Association.

They have both worked through the Joint Mathematical Council in deciding how best the computer needs of schools can be met, not only for class instructional purposes, but for familiarization courses for teachers. The present choice would seem to lie between the central computer based on a university or college of advanced technology, and the travelling computer. There is no support for individual computers for schools.

For the International Congress of Mathematicians at Moscow in 1966, the three topics to be discussed by the International Committee for Mathematics, and their United Kingdom sponsors, are: (a) the programme of university training in mathematics for the future physicist (the Institute of Physics and the Physical Society); (b) the use of the axiomatic method in secondary teaching (the Mathematical Association); (c) the development of mathematical activity in school children; the place of the problem in their development (the Association of Teachers of Mathematics).

### Robbins and All That

Dr. I. W. Busbridge began her presidential address by directing the attention of the large audience in the Sheldonian Theatre to the building designed by a mathematician, Christopher Wren, and to Robert Streater's painted ceiling with its motif 'Truth descending upon the Arts and Sciences', and its mathematical significance.

In this age, if we are to achieve an educated nation, much "blood, toil, tears and sweat" lies ahead. Dr. Busbridge suggested that it was worth considering similar problems which must have faced Britain when the building of the Sheldonian was started in 1664. Galileo had died but twenty-two years before, the Royal Society had just been founded, Wren and Newton were young men, Halley a child, and, with the Commonwealth upheaval, the whole period was a ferment of ideas in many ways similar to our situation to-day. The Visitations at Oxford and Cambridge and their effect were paralleled to those of Robbins on the present university. It was of interest that the appointment in 1647 of John Wallis, for fifty years Savilian professor of geometry, was due to his predecessor being replaced by the Visitors for possessing Royalist sympathies. Both Wren and Halley must have been taught by him. The Visitors tried to impose new statutes on universities and colleges, but then, as now, Oxford demanded the right to take its own government into its own hands and to write its own statutes. Even then there were proposals for new universities, with London, York, Manchester and Durham all claiming consideration, and much outspoken criticism of the older universities. There were advocates for a university for every city, and suggestions for turning universities into scientific and technological institutes. With the Restoration came the reaction against science, and the dedication of the Sheldonian provided the popular preacher, Robert Smith, with an opportunity to damn the new philosophy.

In spite of this reaction, the golden age of British mathematics and mathematical physics blossomed: the time was ripe for Newton, whose *Principia* was initiated, and the printing paid for, by Edmund Halley, whose observatory is still to be seen in nearby New College Lane. This new learning found its way into the schools, and men such as Dr. Thomas Gale of St. Paul's School, later a Fellow and Secretary of the Royal Society, were firing the minds of boys like the young Halley. An important experiment in mathematical education was the foundation in 1673 of the Royal Mathematical School at Christ's Hospital to provide navigators for the Royal

Navy and merchant marine—an early technical section of a comprehensive school. The foundation had the benefit of advice and help from Sir Jonas Moore, inspector general of Ordnance, and one of the best practical mathematicians of the day, and the continuing interest of Newton, Flamsteed, Wren and Pepys, all governors of the school. Halley, who lived nearby, helped with the publication of the text-book on navigation. Unfortunately there was—just as now—a shortage of teachers of mathematics, and, in 100 years, no eminent mathematicians were produced by this School.

Before coming to the problems of the present day, Dr. Busbridge referred to a later 'Robbins Report'—the Royal Commission on the Universities of 1850. Although some steps had been taken before 1850 to establish degrees in science at Oxford and Cambridge and the setting up of laboratories at Balliol and Christ Church, the Commissioners made enlightened proposals regarding the provision of a School of Mathematics and Physical Sciences with two departments: (a) Pure and Applied Mathematics; (b) Mechanical Philosophy, Chemistry and Physiology, together with subordinate science. They also proposed that proficiency in mathematics might compensate for weakness in Latin in a new matriculation examination. The reactions at Oxford were violent, but reforms came steadily.

Turning to the Robbins Report itself, Dr. Busbridge considered the recommendations for a two- or three-subject degree to include mathematics, since "the great majority of undergraduate students of mathematics have neither the aim nor the ability to become mathematicians of the front rank, and, for them, somewhat less concentration would be appropriate, in order to make way for the study of some other suitable subject such as physics or chemistry". Dr. Busbridge, while completely in favour of two-subject courses involving mathematics provided such a course is well integrated, was concerned at the definition of 'front-rank' mathematicians. Assuming that such a mathematician is one capable of profiting from a postgraduate course in advanced mathematics, that is, those with first and top seconds in Finals, she disagreed profoundly with the suggestion that all the rest would be better doing two-subject degrees. It is well known that almost one-third of the students entering mathematics courses fall by the way. The proposals were: (a) more help and guidance to be given to first-year mathematics students—the year which even quite able students find difficult; (b) grants should be extended to allow mathematics honours failures to transfer to a double-subject honours course (this policy is understood to be now accepted in principle); (c) a lowering of the standard of the first-year course. However, she appreciated that each university must solve the problem for itself.

Dr. Busbridge was next concerned with the shortage of teachers of mathematics and, with the increased requirements of the universities and other colleges of further education, she feared a shortage in the schools for some time to come. The Oxford system of lectures to perhaps 150 undergraduates, with a wide range of abilities, made it desirable that there should be an adequate backing of tutorials; but this again created a staffing problem, though without two-way traffic at all levels, lectures cannot expect to be successful. The tutorial system is equally good for the "embryo Newton", the steady-going second-class man, and for the man at the bottom of the list. Dr. Busbridge did not advocate the abolition of the Oxford entrance and scholarship system. Her experience showed that among her most able students were those who on the results of the Advanced Level Examination for the General Certificate of Education would never have been selected.

The new school mathematics courses are bound to create problems over the next few years, and universities will have to design their first-year courses over that period so that all students arrive at the second year with a common basis of knowledge. This must be done without

boring "modernists" who have been stimulated in their schools or confusing the "traditionalists" by not laying a true foundation for the new work. The Association's Universities and Schools Committee is trying to compile a basic syllabus which would be common to all Advanced Level courses for the General Certificate of Education and without which a first-year university course would be unintelligible. This basic syllabus would also be the backbone of the one-subject Advanced Level course, thus facilitating the transfer from science courses to mathematics.

Dr. Busbridge appealed for more experimentation in schools. She did not expect them to go all the way with some of the new projects, but hoped teachers would endeavour, whenever appropriate, to make injections of modern mathematics into the traditional system. This would stimulate both teacher and pupil. Syllabuses were never intended to be adhered to rigidly. Every teacher of mathematics has two objects: (a) to give to every student the opportunity of developing his or her mathematical powers to the full; (b) to foster those of special ability for the sake of the country as a whole and for the advancement of knowledge. Dr. Busbridge criticized the Leicestershire form of comprehensive schooling (with its junior and senior high schools) as it is likely to affect the fulfilment of these objects. The years twelve to fifteen are the most important in the production of the mathematician, yet, under the Leicestershire scheme, experience is showing that few qualified mathematicians are opting to teach in the junior high schools. For Britain to survive we have to increase the supply of mathematicians, and yet many local authorities are turning to the Leicestershire plan as the solution to all their difficulties. In the true comprehensive school no such difficulty is created. She considered that the Mathematical Association should press for a dovetailing of time-tables between the junior and senior high schools under the Leicestershire plan so that at least the 'A' streams would be taught by fully qualified mathematicians. In the universities the process of levelling up or levelling down is also working. Whatever happens, this must be a levelling up, since Britain needs the best mathematicians that she can produce if the 'brain drain' is ever to be slowed and a reverse flow stimulated. Eminent research schools must be built up which will provide such intellectual and material attractions that many of the ablest young mathematicians and scientists will choose to study in them.

In conclusion, Dr. Busbridge, viewing all the difficulties ahead, took heart from the past surrounding her audience. Life under the Puritans must have been pretty grim, and yet it was the continuing effort of men with vision and faith that brought in the golden age of British mathematics. Now, as in 1885, we need the vision of Christopher Wren and Robert Streater when they chose 'Truth descending upon the Arts and Sciences' as the subject for their great painted ceiling.

#### The Mathematical Association, the Institute of Mathematics and the Joint Mathematical Council

The first discussion of the conference was on what the foregoing bodies do for the teacher of mathematics, and was opened by Prof. T. A. A. Broadbent on the Mathematical Association, and Prof. J. G. Semple on the Institute of Mathematics and Its Applications and the Joint Mathematical Council.

Prof. Broadbent challenged members as to whether they were accepting their individual responsibility to see that things which needed to be done were done. In his view, the Association to-day offered very good value to members for their subscriptions, with a first-class *Gazette*, frequent reports, ample branches, diplomas, etc.

The Association's primary purpose is the teaching of mathematics, but we must appreciate that the mathe-

matics is at least as important as the teaching. We must teach good mathematics in a good way.

He was sorry to note how few of the younger university dons and lecturers were members. This he felt to be a bad thing on a number of counts, but particularly for the inevitable widening which must result in the gap between the universities and the schools, a gap which only the Association is qualified to fill.

Prof. Broadbent hoped to see more young men and women playing their full part in the activities of the Association, and charged the older members to see that this was possible and encouraged. This is not a matter of what 'they' should do; it is a 'do-it-yourself' problem.

Prof. Semple, secretary of the Joint Mathematical Council, outlined the steps which have led in the past two or three years to the setting up of a Joint Mathematical Council of the United Kingdom, and of an Institute of Mathematics and Its Applications. He paid tribute to the part which the Mathematical Association, and in particular Mr. J. T. Combridge, had played in their inauguration.

In addition to setting up the Institute of Mathematics and dealing with international conference matters, the Joint Mathematical Council has been mainly involved with two projects which both affect the teacher: (a) the setting up, under the Organization for Economic Co-operation and Development, of a national committee, under the chairmanship of Dr. E. Kerr (Salford Royal College of Advanced Technology), to report on mathematics as a component of the training of engineers to first-degree level in Great Britain; (b) the formulation of plans for improving the standard of mathematical instruction in schools and increasing the supply of trained mathematicians.

Dr. Kerr's committee has worked out a 'core' syllabus in mathematics for engineers which contains a substantial section on numerical analysis and computer programming science. It has also prepared a suggested Advanced Level syllabus which would provide the kind of school mathematical training most useful to engineers.

Discussions are now proceeding with the appropriate institute on how time for this core syllabus can be found from that at present allocated to other engineering subjects, and how mathematics departments generally are to equip themselves to teach in the spirit envisaged in the report from the Organization for Economic Co-operation and Development.

The Joint Mathematical Council's most difficult project has been that of the present complex of problems relating to mathematical instruction in general, and particularly in schools, both primary and secondary. The Council's approach to this problem has been taken under three main heads: (a) the possible danger of the threatened proliferation of General Certificate of Education syllabuses, and the possibility or desirability of some degree of control, for example, by means of agreed minimal core syllabuses at the various levels; (b) the provision of a regular and effective information service for all teachers of mathematics; (c) the expansion, both for the present emergency and on a permanent basis, of facilities for the in-service training of teachers of mathematics in schools.

To try to reach a decision on (a), the Joint Mathematical Council has charged all its constituent member associations, covering the university-level to the primary school, to examine this problem independently and to report back to the Education Committee of the Council on which selected Her Majesty's Inspectors of Schools are attending members.

The foregoing items (b) and (c) have not posed the initial problems that (a) has done and is likely to do. Recommendations for the in-service training of teachers and for the setting up of an information service for teachers have already been welcomed by the Minister of State for Education and are now under his consideration. These proposals include the setting up for the development

of in-service training of teachers of: (a) local mathematics centres (each located in a school and covering a considerable group of primary and secondary schools in a local education authority neighbourhood); (b) regional advisory units (based on institutes of education); (c) a national committee. In addition, it is proposed that a national information centre should be established, located possibly in one of the larger institutes of education.

The subsequent discussion showed that the Association was very conscious of its failure to make an impact in the primary field and that the fault lay in the first instance with the members, who had failed to accept their responsibility as mathematicians to help to bridge the gap. Courses and lectures were arranged, but secondary and university teachers were all too conspicuous by their absence.

### Mechanics Report and Other Discussions

The second and third discussions of the conference were on the Association's recently issued second reports on the teaching of mechanics and arithmetic in schools.

The Mechanics Report was described by the president as one of the Association's outstanding reports and a great addition to its literature.

Mr. J. T. Combridge, chairman of the Report Sub-Committee, outlined some of the thoughts which had guided its preparation. While applied mathematics is tending to disappear from the examination syllabuses, there is still plenty of applied mathematics which needs to be taught. It is a suitable subject for all secondary pupils whatever the age or ability, and it should provide the opportunity for co-operation with teachers of science subjects. It is most certainly not a dead subject: it is indeed a live and developing subject and teachers should endeavour to make it a live subject in keeping with modern times, whether by experiment or other means. The report endeavours to lead.

Mr. S. L. Parsonson (Harrow School) described the report as a spirited plea for the retention of a subject which surely must be needed in times when the demand for technologists, applied mathematicians, and scientists capable of doing applied research is so great. He blamed the examination system of the past twenty or thirty years for the subject's present disrepute. It has removed the subject from the real world into that of unreal problems, and any questions set involving a test of the principles of mechanics soon showed the students have a serious lack of understanding of the basic principles.

The only major criticisms of the report from the floor emphasized that frames of reference were not sufficiently stressed and that insufficient attention was directed to the needs of the teachers at the Certificate of Secondary Education level who need more guidance than their more highly mathematically qualified colleagues.

The problem of the mathematical model and the difficulty of setting examination questions which are both sensible and soluble at the appropriate level was one to which no ready answer was given. All were agreed on the early introduction of the use of vectors.

The Arithmetic Report (a completely new report to replace the previous 1931 report) was described by Mr. C. G. Nobbs, a member of the Report Sub-Committee, as one based on the concept that computation, seen as a mechanical process, is being left increasingly to the machine, and that the time thus saved allows a more informal approach leading to better understanding.

Mr. Ellerby (St. Dunstan's, Catford), speaking as a junior school master, felt that the report should have given more guidance, though this view was not supported from the floor. Many felt that teachers must be prepared to consider alternative methods which may seem equally desirable, weigh them and make up their own minds.

Some speakers would have liked to see statistics, as a branch of arithmetic, receiving even greater emphasis in the report.

The final discussion of the conference was on school mathematical societies. The main speakers were Mr. D. Hobbs (Exeter School) and Mr. A. R. Tammadge (Abingdon). Mr. Hobbs outlined the activities of an essentially practical society which thrived on the making of mathematical machines and models of all types, working computers being demonstrated. Mr. Tammadge spoke of the more culturally inclined senior society the *modus vivendi* of which was based socially and intellectually on that of the university society.

### General Lectures

Dr. J. F. Scott, deputizing for Prof. McKie, gave the Association a most absorbing account of the early history of the Royal Society up to the early eighteenth century.

Prof. M. F. Atiyah, Savilian professor of geometry in the University of Oxford, speaking on "Linear and Non-Linear Mathematics", took members to some of the frontiers of mathematics to-day, indicating the unity and simplicity of the subject. He showed the significance of linear methods in various parts of mathematics and the advantages in translating certain kinds of non-linear problems into linear form: in this, one does not restrict oneself to finite dimensional linear problems but allows infinite dimensions.

Dr. K. Austwick, Department of Education, University of Sheffield, in an illustrated lecture entitled "Automation in the Classroom", gave a balanced idea of the way in which teaching machines can be used as an aid in the teaching of mathematics. The present machines, which are relatively unsophisticated, are mainly effective in the teaching of motor skills and are more useful for revision, remedial and self-tutoring work with students capable of constructing responses. Conventional teaching

cannot fail to benefit. In this respect his concluding remark was very pertinent: "Any human teacher who can be replaced by a machine ought to be".

Mr. J. H. Durran (Winchester College), speaking under the title "Do-it-yourself  $\chi^2$ ", delightfully demonstrated how the testing of goodness of fit in statistical work can be approached in an intuitive and experienced way.

The final lecture and film of the conference was "I Do and I Understand—a New Look at Primary School Mathematics", by Mr. J. W. G. Boucher, a former primary school teacher, and now a Fellow of the Nuffield Research Foundation. The attendance and interest shown by members at this final lecture showed that there is an increasing awareness among mathematicians that, using as practical an approach as possible with young children, mathematics can become the favourite subject for all children.

### Elections and Future Conferences

At the annual general meeting, Mrs. E. M. Williams was elected president for 1965–66. The following honorary officers were re-elected. *Treasurer*, Mr. R. E. Green; *Secretaries*, Mr. F. W. Kellaway and Miss R. K. Tobias; *Editor*, Dr. E. A. Maxwell; *Librarian*, Prof. R. L. Goodstein; *Assistant Secretaries*, Mr. K. J. Backhouse, Instructor Captain R. G. Cross, Mr. B. J. F. Dorrington, Miss E. M. Holman, Dr. E. Kerr and Mr. C. Steele; *Assistant Treasurer*, Mr. N. Q. Dodds.

The 1966 meeting will be held in the University of North Staffordshire during April 13–16, 1966. The centenary meeting (1971) is being planned for University College, London, where the inaugural meeting of the Association for the Improvement of Geometrical Teaching (now the Mathematical Association) was held in 1871.

R. G. CROSS

## SIXTY THOUSAND PERIODICALS

THE *World List of Scientific Periodicals*\* was initiated late in 1920, when Sir Sidney F. Harmer, director of the Natural History departments of the British Museum, wrote to Sir Peter Chalmers Mitchell, secretary of the Zoological Society of London, asking him to direct the attention of the Conjoint Board of Scientific Studies to the problems of what is now referred to as information retrieval. The multiplicity of periodicals, issued in various languages throughout the world, was already confusing. No single library held more than a fraction of the total number, and the Board was invited to consider the preparation of a list of scientific periodicals with an indication of the libraries where they were kept.

The Board adopted the suggestion, and work began late in 1921, under the guidance of the World List Association, incorporated as a limited company. The first edition concerned the years 1900–21; it was issued in two volumes of which the first, published in 1925, listed 24,128 titles, while the second volume, published in 1927, gave standard abbreviations and library locations. The second edition was issued in one volume in 1934, and covered the years 1900–33; the third edition, covering 1900–50, was issued in 1952 and reprinted in 1958. The present edition covers the years 1900–60 so that, like its predecessors, it attempts to include every periodical which survived into the present century. About a quarter of the entries are titles published since 1950 and the total number is now more than 60,000, and the *List* is now issued in three volumes. In spite of the inconvenience in handling

which is inevitable in a multi-volume work of reference, this edition is even more generally useful, and readily consulted, than its predecessors. A new type-face has been employed, words used in the alphabetical arrangement are in bold type, and the number of cross-references has been increased. The transliteration of Cyrillic and Greek alphabets is in accordance with the recommendation of the Royal Society, modified and published as British Standard 2979: 1958.

The abbreviation of titles of scientific periodicals according to a carefully considered system, which has been a feature of the *World List* since its inception, has been instrumental in effecting a degree of uniformity in bibliographic usage throughout the scientific world. The abbreviations in this edition follow a forthcoming British Standard, not greatly different from the system followed in previous editions.

This is to be the last edition of the *World List* compiled and produced in this way, by an Association which has no permanent staff and by editors whose main occupation is elsewhere. The first three editions were prepared under the supervision of the late Mr. W. A. Smith, of the British Museum. After his death, before work on the fourth edition was begun, Mr. Peter Brown, also of the British Museum, undertook the editorship with Mr. G. B. Stratton, of the Zoological Society, who has been associated with the *World List* from its earliest days. The Association has had four successive chairmen: Sir Peter Chalmers Mitchell, Dr. A. S. Neave, Dr. E. J. Holmyard, and the present chairman, Dr. L. Harrison Matthews. In future, it is proposed to continue the *List* in the form of an annual cumulation of the material published quarterly by *Bucop*, the British Union Catalogue of

\* *World List of Scientific Periodicals Published in the Years 1900–1960* Edited by Peter Brown and George Burder Stratton. Vol. 1: A–H. Pp. xxv+1–532. Vol. 2: I–P. Pp. xx+533–1196. Vol. 3: Q–Z and Periodic International Congresses. Pp. 1187–1824. (London: Butterworths, 1963, 1964 and 1965.) 500s. per set of three volumes.

Periodicals, published by the National Central Library. It is hoped that it will be possible to prepare 5- and 10-year compilations, offering to the user the convenience of the present compilation and incorporating the name *World List* in the title. *Bucop* employs a computerized system and the National Central Library commands resources commensurate with the immense amount of material which it will be necessary to handle.

The possibility of providing an index, to assist (for example) in tracing a periodical the title of which is incompletely known, is being borne in mind by the compilers of the computerized catalogue. It could hardly be expected within the framework of the *World List* as it is to-day. This edition is not absolutely free of errors, but it is clear that it has been most meticulously

prepared. It is obviously impossible to guarantee the inclusion of every scientific periodical in a list compiled from information volunteered by contributing libraries the stocks of which may not include every publication that could qualify. However, the number of libraries contributing to the present edition has been increased and, by courtesy of the Director, the compilers have had access to a number of titles held in the National Lending Library for Science and Technology, which was not officially opened until 1962.

Many new journals have been started since 1960, but nevertheless these three volumes provide an invaluable guide to all but a small fraction of the periodical literature a scientist may wish to consult, and to its whereabouts in British libraries.

## FIELD STUDIES COUNCIL

ACCORDING to the latest annual report of the Field Studies Council\*, the year 1963-64 saw a continuance of the growth in the number of students attending the Council's centres. The total number of student-weeks reached 11,617 (an increase of 12 per cent)—mainly as a result of additional accommodation at Slapton Ley and of a full season at Orilston, but also because of larger bookings at other centres. This was divided between subjects as follows:

Biological subjects	5,979
Countryside and natural history	232
Geographical and geological	4,686
Art	245
Archaeology	219
Other courses	196

The number of individual attendances as distinct from the number of student weeks was 11,629, divided as follows:

Sixth forms	7,736
Other forms	192
Training colleges and teacher courses	1,569
Universities	1,160
Technical colleges	145
Amateurs	827

Despite the extra numbers which the centres have been able to take, many hundreds of would-be students had to be turned away. It is the Council's aim and intention to open further centres when the necessary finance becomes available, and the New Centres Working Party is con-

tinuing its search for suitable properties in areas where centres might be established. The Council was greatly heartened in the early part of the year to learn that the Worshipful Company of Drapers was proposing to make a grant of £25,000 to it to mark the occasion of the sixtieth anniversary of the granting of the Company's first charter. Payment is to be made by instalments over a period of not more than five years; a condition of the grant is that it shall be used for purchasing and converting a property situated in North Wales to a field studies centre. Search immediately began for a suitable building. It was decided that the property most suitable to the Council's requirements was Rhyd-y-Creua, a house situated in the Conway Valley, one mile from Betws-y-Coed. Rhyd-y-Creua is unlikely to be ready to accommodate students before the 1966 season commences.

Following the recommendation of the Scientific Advisory Committee, Preston Montford and Slapton Ley have been inspected by the Department of Education and Science, the reports of which are now being awaited. Preston Montford was also visited by two scientists from the Sub-committee and as a result of their report and suggestions a new experimental biology course was inaugurated which, after one season, is considered to be very successful.

A small working party has been set up, the brief of which is to consider the educational aims and practice of the Field Studies Council in the light of present and future needs and to make recommendations to the Council.

## PHILOSOPHIES OF PIERRE TEILHARD DE CHARDIN

I FIRST met Pierre Teilhard de Chardin as a young man, when we were assisting in prehistoric investigations in north Spain in 1912 or thereabouts. I also had occasion to see him from time to time until his death. He had a charming personality and was an excellent research worker in the fields of palaeontology and geology, and did much administrative work while living in China. He read deeply in the realm of philosophy, and was accepted wholeheartedly by others practising in that discipline. Above all, he was a profound Christian—a Roman Catholic and indeed a Jesuit. Not many men have reached the front rank in all these three disciplines, and therefore what he has to say is worthy of great consideration.

Teilhard was a firm believer in evolution—indeed, he was to some extent persecuted by his own hierarchy for

this belief—but he did not confine evolution to living organisms; for him everything from the atom to reflective man has been influenced by evolution. He made no distinction between man and the animals, nor indeed between animate and inanimate objects. Matter had 'pre-life', an imperceptible particle of life, and was therefore also influenced by evolution. At present the effects of evolution tend to divergence, but in the case of reflective man must ultimately converge towards a unity which he called omega. For Teilhard this omega was equated with the incarnation, birth, life, death and resurrection of Jesus, the Christ.

Such a bald series of statements is, of course, grossly inadequate. It takes many hours of hard study properly to appreciate the width and depth of Teilhard's thought. It is a great pity that the older generation of Jesuits in

the 'twenties failed to recognize what a great man he was. They seldom allowed him to come to Paris, and he mostly lived and worked outside his native France. He died in 1955 in the United States. Only after his death was it possible for his great books to be properly produced. The Abbé Breuil once told me that what he was able to publish during his lifetime was only because he chanced to be a friend of the then Pope. Several times friends suggested that he should cease to be a Jesuit. But Père Teilhard was loyal both to his Church and to his Order.

*Pierre Teilhard de Chardin—Some Aspects of his Thought\** is an admirable introduction to certain aspects

\* Proceedings of the University of Newcastle upon Tyne Philosophical Society, Vol. 1, No. 8: *Pierre Teilhard de Chardin—Some Aspects of his Thought*, P. G. Fothergill, Pp. 24–84. (Newcastle upon Tyne: University of Newcastle upon Tyne Philosophical Society.)

of his philosophies. It should be read before attempting to tackle the great life by Claude Cuénot, or indeed the two major works of Teilhard himself, namely, *The Phenomenon of Man* and *Le Milieu Divin* (the French title has been retained in the English translation). Not everyone after careful study will entirely agree with Teilhard's thought. There will always be those who separate entirely the soul of man from the rest of creation and treat it like the mistletoe on an apple tree, which for a time is bound to the tree yet is really totally distinct. But Teilhard's philosophy is worthy of very careful thought, and anyone interested cannot do better than to read carefully Fothergill's *Pierre Teilhard de Chardin: Some Aspects of his Thought*.

M. C. BURKITT

## ONCOLYSIS WITH LASER ENERGY COMBINED WITH CHEMOTHERAPY

By JOHN PETER MINTÓN

Surgery Branch

AND

PROF. GEORGE H. WEISS and PROF. MARVIN ZELEN

Biometry Branch, National Cancer Institute, National Institutes of Health, Bethesda, Maryland

RECENT experiments have shown that pulsed laser energy can be used for the rapid and precise destruction of malignant tumour implants in animal systems<sup>1</sup>. It has been shown quantitatively that the probability of destroying a tumour implant in a mouse depends on the ratio of laser energy to tumour size. The destruction probability increases with this ratio in a manner which can be made mathematically precise<sup>2</sup>.

It is the purpose of this article to report on experiments where chemotherapy has significantly increased the destructive effect of laser energy on the tumour system. Other investigators<sup>3,4</sup> have also attempted to find a way for potentiating the destructive effects of the laser energy on tumour systems. These investigations involved painting the surface of a tumour with a dye or systemically injecting various pigmented solutions into the animal. The results by these methods have been relatively unsuccessful.

The results of experiments comparing the effect of laser energy alone with the combination of laser energy and a course of cyclophosphamide on tumour-bearing mice are summarized here. The results show that permanent tumour destruction by laser energy is significantly increased in mice receiving cyclophosphamide as compared with mice not receiving this course of chemotherapy.

The experiment consisted of injecting 115 six-week-old CDF<sub>1</sub> female mice with 0.04 c.c. of a 1:10 dilution of Cloudman S91 melanoma<sup>5</sup>. At the end of two weeks of tumour growth, the animals were arranged in order of size of tumour which ranged from 1 mm to 10 mm in diameter. The animals were paired according to size such that animals in a pair had tumours of comparable size. Among the 57 pairs, 11 pairs were designated as 'control pairs'; the remaining 46 were termed 'treatment pairs'. The control pairs were assigned to every fifth pair in order of size of tumour. One animal in each of the control and treatment pairs then received an 11-day course of cyclophosphamide chemotherapy injected subcutaneously at a daily dosage of 25 mg/kg/day. At the end of the fifth or sixth day of chemotherapy, all the animals in the treatment pairs were exposed to laser energy. Animals in the same pair received the same amount of energy from a ruby laser (6889 Laser Unit—Maser Optics, Boston, Mass.). The ruby rod was 1.6 cm in diameter and 17.7 cm in length and utilized a Fabry-Perot etalon dielectric coating for internal reflexion. It was stimulated

by two 7.5 kW xenon flash lamps. The laser energy was delivered in several pulses, each of which was 48–56 joules. Energy determinations were obtained by direct calorimetry at varying intervals between the series of tumour exposures. Each laser pulse was delivered through a biconvex lens with a 12.5 cm focal length.

In order to destroy a tumour, it is necessary that the entire tumour be exposed to laser energy. Therefore, large tumours (greater than 5 mm in diameter) received multiple pulses. Animals were observed for five weeks after exposure to the laser energy.

There were 42 treatment pairs in which results could be evaluated; the death of two mice invalidated results from two other pairs. These results are summarized in Table 1.

The only experimental results which can be used for evaluating the comparison between the two treatments are those pairs in which the tumour on one mouse was destroyed, while the other mouse's tumour recurred.

There were 15 such pairs. Of these, 14 showed tumour destruction by the combination of laser and chemotherapy with tumour recurrence on the paired mouse which received laser only. Clearly this is a highly significant result.

The effect of chemotherapy before irradiation by laser energy was to decrease the growth rate of the tumour. Consequently at the time of laser radiation, the animals receiving chemotherapy had tumours which were (on the average) slightly smaller than those receiving no chemotherapy. The average (geometric) diameters were 8.27 mm and 7.92 mm for the non-chemotherapy and chemotherapy animals respectively.

In order to determine if the slight difference in tumour size could possibly account for the potentiation observed with the chemotherapy, the animals were paired a second time (after being exposed to the laser energy). The animals in the same pair received the same amount of laser energy, but this time the (geometric) diameters of the tumour at the time of laser exposure were matched. This classification yielded pairs, in which the average

Table 1 RESULTS OF TREATMENT PAIRING  
(Pairing done before chemotherapy)

	15	43

diameter of the non-chemotherapy and chemotherapy animals was 7.97 mm and 8.01 mm respectively. The experimental results for this second pairing are summarized in Table 2. The number of pairs for which the

		Tumour destroyed	Tumour recurred	
		1 9 10	1 20 21	2 29 31

outcome for both animals was different is 10. Of these, 9 were favourable to the combination therapy. Again these results are highly significant ( $P=0.026$ ).

An incidental observation was that tumours which recurred after laser radiation appeared to grow at a much faster rate than before being irradiated. In contrast, recurrent tumours after combination chemotherapy and irradiation had a reduced growth rate (in comparison to normal tumour growth rate).

## MAGNETIC AND SPECTRAL EVIDENCE FOR TRINUCLEAR CLUSTERS IN MOLYBDENUM CHLORIDES

By DR. R. COLTON and PROF. R. L. MARTIN  
 Department of Inorganic Chemistry, University of Melbourne

IN a recent communication<sup>1</sup> we directed attention to the fact that compounds involving polynuclear metal clusters are not necessarily diamagnetic, and that paramagnetism can often be of diagnostic value for detecting the presence of metal-metal bonding. If a core is constituted of an odd number of metal atoms with uneven electron configuration, the cluster is likely to be weakly paramagnetic and to obey Curie's Law. Thus, the low magnetic moment of rhenium (IV) chloride,  $\mu_{\text{eff}} = 1.0$  Bohr Magnetons (B.M.) is independent of temperature and is consistent with a trinuclear species  $\text{Re}_3\text{Cl}_{12}$  with a single unpaired electron distributed over the  $\text{Re}_3$ -core<sup>1</sup>. On the other hand, if the core contains an even number of metal atoms, diamagnetism is generally observed (for example,  $[\text{Mo}_4\text{Cl}_{14}]^{4+}$ ,  $[\text{W}_4\text{Cl}_{14}]^{4+}$ ,  $[\text{Ta}_4\text{Cl}_{14}]^{3+}$ ) (refs. 2 and 3), although paramagnetic species may also be found (for example,  $\text{Mo}_4\text{Cl}_{14}$ ,  $[\text{Cr}_4\text{Cl}_{14}]^{3+}$ ,  $[(\pi\text{-cpd})_4\text{Ti}_4\text{Cl}_{14}]$ , refs. 4-6).

Table 1. MAGNETIC PROPERTIES OF MOLYBDENUM (III) CHLORIDE

Temp. (°K)	$\chi_M \times 10^3$	$\mu$ (B.M.) = $2.84 [ \chi_M(T+100) ]^{1/2}$
300	309	1.00
281	320	0.99
256	335	0.98
231	360	0.98
209	377	0.97
158	466	0.99
141	495	0.98
115	546	0.97
91	643	1.00

An early investigation<sup>7</sup> of the magnetic properties of molybdenum (III) chloride at three temperatures showed that the magnetic moment was about 0.8 B.M. This value is anomalously low for molybdenum (III) compounds, which usually show magnetic moments of the order of 3-8.3 B.M.<sup>8</sup>. We have now investigated in detail the variation of the magnetic susceptibility of molybdenum (III) chloride with temperature and find our results agree well with those of Klemm and Steinberg<sup>7</sup>. Extrapolation to infinite susceptibility of a plot of  $\chi_M^{-1}$  against  $T$  (Curie-Weiss plot) shows the presence of an antiferromagnetic interaction with a  $\theta$ -value of 100°. With the inclusion of this term the magnetic moment of molybdenum (III) chloride is 1.0 B.M. and independent of temperature. This suggests that the compound is also a trimer  $\text{Mo}_3\text{Cl}_9$  with the ground state configuration  $(a_1')^2(a_1'')^2(e')^2(e'')^1$  isoelectronic with that of  $\text{Re}_3\text{Cl}_{12}$  (ref. 1). The deviation from a true Curie law is not unexpected if the compound has a structure of the same

type as that found for rhenium (III) chloride, the weak antiferromagnetic interactions occurring via bridging chlorine atoms joining the adjacent trimer units<sup>9</sup>. The experimental results are presented in Table 1.

The diffuse reflectance spectrum of molybdenum(III) chloride is not unlike those of the  $\text{Re}$  (III) clusters examined by Cotton *et al.*<sup>9</sup> with well-defined absorption peaks at 530 m $\mu$  and 760 m $\mu$ , as shown in Table 2.

Table 2. SPECTRA OF MOLYBDENUM CHLORIDE CLUSTERS

Compound	Electron configuration	Positions of absorption maxima, cm <sup>-1</sup> ( $\epsilon_{\text{max}}$ )	Solvent
$\text{Mo}_3\text{Cl}_9^{3+}$	$d^3$	14,100 (160), 21,500 (1,550)	Acetonitrile
$\text{Mo}_3\text{Cl}_9$	$d^3$	13,150; 19,100	Reflectance
$\text{Re}_3\text{Cl}_{12}$	$d^1$	13,300 (410); 19,400 (1,610)	Acetone <sup>9</sup>

Our evidence for the trinuclear nature of molybdenum (III) chloride is at variance with unpublished data quoted by Schafer and Schnering<sup>10</sup>, who suggest that the compound contains  $\text{Mo}_4$ -clusters and is diamagnetic ( $\chi_M = 19 \times 10^{-4}$  o.g.s., B.M.U.). The trichlorides of several transition metals, notably those of titanium<sup>11</sup>, rhenium<sup>12</sup> and ruthenium<sup>13</sup>, are known to exhibit polymorphism; possibly Schafer prepared a different polymorph. The material used in our investigations was prepared by thermal decomposition of molybdenum (V) chloride in nitrogen, the temperature being kept as low as possible to avoid further decomposition to molybdenum (II) chloride. Preliminary attempts to ascertain, by X-ray powder methods, whether  $\text{MoCl}_3$  and  $\text{ReCl}_3$  are isostructural are inconclusive, although the diffraction patterns of the two compounds are similar.

Mr. D. F. Stewart and Dr. T. A. O'Donnell, of this Department, have recently succeeded in isolating a chloro-cation of molybdenum (IV),  $[\text{MoCl}_4]^+$ . The magnetic moment of this species lies between 1.6 and 1.7 B.M. and the Curie law is obeyed. The electronic spectrum of solutions of the cation in acetonitrile closely resembles those of other  $d^3$  and  $d^4$  trimers, which suggests that this cation should be formulated as  $[\text{Mo}_3\text{Cl}_9]^{3+}$ . Reference to the M.O. diagram<sup>1</sup> shows that the expected ground state electronic configuration of  $(a_1')^2(a_1'')^2(e')^2$  should be associated with two unpaired electrons per  $[\text{Mo}_3\text{Cl}_9]^{3+}$  trimer with a corresponding magnetic moment of 1.64 B.M., that is, 2/3 of an electron per molybdenum (IV) atom. Preliminary magnetic measurements on molybdenum (IV) chloride, tungsten (V) chloride and tungsten (V) bromide suggest that these compounds also involve trinuclear clusters, the latter compounds existing as  $[\text{W}_3\text{Cl}_{12}]^{3+}$  and  $[\text{W}_3\text{Br}_{12}]^{3+}$  cations.

Mo (V)	[Mo <sub>2</sub> Cl <sub>12</sub> ] <sup>+</sup>	[Mo <sub>2</sub> Cl <sub>12</sub> ] <sup>+</sup>	[Mo <sub>3</sub> Cl <sub>15</sub> ] <sup>2+</sup>
Mo (IV)	[Mo <sub>2</sub> Cl <sub>12</sub> ] <sup>0</sup>	[Mo <sub>2</sub> Cl <sub>12</sub> ] <sup>0</sup> [Mo <sub>3</sub> Cl <sub>15</sub> ] <sup>+</sup> [Mo <sub>3</sub> Cl <sub>15</sub> ] <sup>0</sup>	[Mo <sub>3</sub> Cl <sub>15</sub> ] <sup>+</sup>
Mo (III)	[Mo <sub>2</sub> Cl <sub>12</sub> ] <sup>-</sup>		[Mo <sub>3</sub> Cl <sub>15</sub> ] <sup>0</sup>
Mo (II)	[Mo <sub>2</sub> Cl <sub>12</sub> ] <sup>-</sup>	[Mo <sub>2</sub> Cl <sub>12</sub> ] <sup>-</sup>	[Mo <sub>3</sub> Cl <sub>15</sub> ] <sup>-</sup>
Mo (I)	[Mo <sub>2</sub> Cl <sub>12</sub> ] <sup>-</sup>	[Mo <sub>2</sub> Cl <sub>12</sub> ] <sup>-</sup>	[Mo <sub>3</sub> Cl <sub>15</sub> ] <sup>-</sup>

The pronounced tendency of molybdenum to form metal-metal bonds in the +2 oxidation state is well known. We have also obtained evidence, to be presented later, that metal-metal interaction occurs in dimeric molybdenum (V) chloride. The results presented here demonstrate that this tendency is not restricted to these oxidation states but is common to all the established oxidation states of molybdenum other than +6.

An interesting progression in the complexity, *n*, of halide clusters with varying oxidation state of the metal atom emerges from these investigations (Table 3). The inverse relationship can be rationalized in terms of the suggestion of Cotton and Haas<sup>1</sup> that the preferred structure is one which will minimize the electrostatic charge carried by the cluster. Table 4 summarizes the possible

clusters of molybdenum chlorides in all six oxidation states on the basis that they adopt one of the established Mo<sub>2</sub>Cl<sub>12</sub>, [Re<sub>2</sub>Cl<sub>12</sub>]<sup>2+</sup> (or Re<sub>2</sub>Cl<sub>9</sub>), or [Mo<sub>3</sub>Cl<sub>15</sub>]<sup>4+</sup> structures.

The clusters known to exist (enclosed by full lines in Table 4) conform both to the foregoing electrostatic requirement and that of filling only those metal-metal molecular orbitals which are bonding.

We assume here that molybdenum (III) chloride, like rhenium (III) chloride, achieves the prototype structure (that is, [Re<sub>2</sub>Cl<sub>12</sub>]<sup>2+</sup>) via inter-cluster chlorine bridging of adjoining trimers. On the other hand, the cation [Mo<sub>3</sub>Cl<sub>15</sub>]<sup>2+</sup> derived from trimeric molybdenum (IV) chloride can presumably solvate in donor solvents like acetonitrile.

The implications of Table 4 should be of general validity and not necessarily restricted to the chemistry of molybdenum.

## USE OF COMBINATION BANDS IN THE VIBRATIONAL SPECTROSCOPY OF METAL CARBONYLS

By PROF. J. LEWIS, A. R. MANNING, DR. J. R. MILLER  
and M. J. WARE

Department of Chemistry, University of Manchester

AND

DR. F. NYMAN

Petrochemical and Polymer Laboratory, Imperial Chemical Industries Ltd.,  
Runcorn Heath, Cheshire

THE use of infra-red spectroscopy in inorganic chemistry has now become widespread. It is a particularly valuable method of studying transition metal carbonyl compounds because absorptions around 2,000 cm<sup>-1</sup> can be specifically associated with C—O stretching vibrations.

Metal-carbon stretching and MCO angle deformation modes occur<sup>1-4</sup> over a relatively wide range, 350–700 cm<sup>-1</sup>. The remaining vibrational modes for mononuclear carbonyls, MCM angle bending, probably occur below 250 cm<sup>-1</sup>.

Measurements of the infra-red spectra of carbonyl compounds in the C—O stretching region, 1,700–2,200 cm<sup>-1</sup>, have been used to provide information on molecular stereochemistry and to study variations of bonding in series of compounds. In all but monocarbonyl compounds there are several C—O stretching vibrations, and in order to make a study of bonding it is necessary to know as much as possible about all of them. Many carbonyl compounds are highly symmetrical and consequently only a few of the fundamentals are infra-red active, and even when several are observed their correct assignment may prove difficult. Raman spectra yield more frequencies and polarization data which afford additional means of assignment. Unfortunately the Raman spectra of only

a few carbonyl derivatives are available because the compounds are often coloured and absorb, rather than scatter, the incident radiation, or are decomposed by it. Limited solubility also restricts the use of Raman methods in many cases. Stammreich *et al.*<sup>1</sup> have overcome some of these difficulties by using sources of long-wave-length radiation and their results have greatly extended our understanding of carbonyl compounds.

As an alternative to Raman spectroscopy for determining 'infra-red-forbidden' fundamentals the infra-red combination frequencies can be measured. We have found that, for a large number of carbonyl derivatives, binary combinations of C—O stretching fundamentals occur near 4,000 cm<sup>-1</sup> with extinction coefficients of about 5–30. Such bands have been reported by Jones for the Group VI hexacarbonyls<sup>2</sup> and for nickel carbonyl<sup>3</sup>, and by Jones<sup>4</sup> and Edgell<sup>5</sup> for iron pentacarbonyl, but have not previously been studied in detail.

The commonest type of infra-red active binary combination is that of an 'allowed' with a 'forbidden' fundamental. Direct overtones are less commonly permitted. Thus, by subtraction of the known active fundamental from the combination frequency, a value for the inactive fundamental may be obtained. Our experience is that the error in frequencies so calculated is not likely to exceed 20 cm<sup>-1</sup>,

and is almost invariably such that the calculated frequency is low. Higher-frequency inactive fundamentals are obtained more accurately than lower ones; we think that this results from a partial cancelling of effects due to anharmonicity and Fermi resonances.

These principles may be illustrated by reference to chromium hexacarbonyl. The molecule has  $O_h$  symmetry and there are three fundamental C—O stretching modes, belonging to the representations  $a_{1g}$ ,  $e_g$  and  $t_{1g}$ . Only the  $t_{1g}$  mode is infra-red active and occurs at 1985  $\text{cm}^{-1}$ . Two binary combinations are allowed ( $a_{1g} + t_{1g}$ ), symmetry  $T_{1g}$ , and ( $e_g + t_{1g}$ ) which spans  $T_{1g} + T_{2g}$ . (Lower case is used for fundamentals, for example,  $a_{1g}$ . Capitals are used for symmetries of combination terms.) They are observed at 4,082  $\text{cm}^{-1}$  and 3,985  $\text{cm}^{-1}$ ; subtraction of 1,985  $\text{cm}^{-1}$  yields 2,097  $\text{cm}^{-1}$  and 2,000  $\text{cm}^{-1}$  for the forbidden fundamentals. These figures may be compared with the values 2,100  $\text{cm}^{-1}$  and 2,020  $\text{cm}^{-1}$  recorded in the Raman spectrum and assigned, respectively, to  $a_{1g}$  and  $e_g$  fundamentals. It is probable that the greater accuracy of the  $a_{1g}$  frequency is due to the effects of (1) anharmonicity, which tends to lower both  $a_{1g}$  and  $e_g$  values, and (2) Fermi resonance between the  $T_{1g}$  components of the combination terms which would also lower the calculated  $e_g$  frequency, but would raise the  $a_{1g}$  value in opposition to the anharmonicity effect.

Interpretation of the infra-red spectra of manganese and rhenium carbonyl derivatives presents an interesting problem. The parent compounds are binuclear molecules,  $M_2(\text{CO})_{10}$ , and, in addition to the usual vibrations, the metal-metal stretching mode must be considered. A knowledge of the fundamental frequencies and force constants of metal-metal bonds would be of considerable value. We have measured the spectra of many manganese carbonyl derivatives but discuss here only the parent compounds  $\text{Mn}_2(\text{CO})_{10}$  and  $\text{Re}_2(\text{CO})_{10}$ . The C—O stretching fundamentals and binary combinations are shown in Tables 1 and 2. The Raman spectrum of the colourless  $\text{Re}_2(\text{CO})_{10}$  has also been recorded (Table 3) and enables us to check how correct are the assignments made from binary combinations in the infra-red. The spectra were all measured in carbon tetrachloride solution; they are slightly solvent-dependent, but we shall discuss these variations in later publications. The Raman spectrum of  $\text{Re}_2(\text{CO})_{10}$  was also measured in cyclohexane, in order to observe some of the lower frequency bands masked by carbon tetrachloride lines. Infra-red fundamentals are accurate to  $\pm 0.5 \text{ cm}^{-1}$  combination bands and Raman lines to  $\pm 2 \text{ cm}^{-1}$ .

Manganese carbonyl has a solid-state structure\* in which two CO groups and the metal atoms are co-linear, the remaining CO groups being arranged in two staggered squares as shown in Fig. 1. The metal atoms are displaced outwards from the centres of these squares. The shape is a very good approximation to  $D_{4h}$  symmetry, although the site symmetry is only  $C_2$ . We assume that the  $D_{4h}$

Table 2. SPECTRUM AND ASSIGNMENTS OF $\text{Re}_2(\text{CO})_{10}$			
Observed frequency ( $\text{cm}^{-1}$ )	$\epsilon$	Assignment	Calculated frequency

arrangement is preserved in solution and that rhenium carbonyl is similar. The possibility of the squares being in an eclipsed configuration ( $D_{4h}$  symmetry) cannot, however, be excluded on spectroscopic grounds.

Fig. 1. The structure of manganese carbonyl

The  $D_{4h}$  arrangement gives rise to seven C—O stretching modes belonging to species  $a_1$  (two),  $b_1$  (two),  $e_1$ ,  $e_2$  and  $e_3$ . Their forms are shown in Fig. 2. Only the two  $b_1$  and the  $e_1$  vibrations are 'infra-red allowed' and just three strong bands are found in the 2,000  $\text{cm}^{-1}$  region, which have been assigned by Flitcroft, Huggins and Kaesz\* as shown in Tables 1 and 2. The four remaining fundamentals,  $a_1$  (two),  $e_2$  and  $e_3$ , are Raman active. It may be noted that mutual exclusion of infra-red and Raman lines occurs here, although these molecules are not centrosymmetric.

Table 1. SPECTRUM AND ASSIGNMENTS OF  $\text{Mn}_2(\text{CO})_{10}$

Observed frequency ( $\text{cm}^{-1}$ )	$\epsilon$	Assignment	Calculated frequency
1,980	4,590	$b_1$	—
2,014	25,500	$e_1^*$	—
2,046	12,100	$b_1^*$	—
3,906	<0.1	—	—
3,961	• 10.5	$\{a_1 + b_1, a_1 + e_1, a_1 + b_1^*\}$	3,956
3,990	10.8	$\{e_1 + e_1, e_1 + b_1^*\}$	3,981
4,023	12.5	$\{2a_1, a_1 + b_1^*\}$	3,985
4,035	5.9	$\{e_1 + e_1, 2e_1\}$	3,990
4,061	<0.1	—	3,993
4,096	2.9	$a_1^* + b_1$	4,023
4,109	<0.1	—	4,032
4,125	24.3	$a_1^* + e_1$	4,035
4,163	7.3	$a_1^* + b_1^*$	4,036

Fundamental:  $a_1^*$   $e_1$   $b_1^*$   $b_2$   $a_1$   $e_1$   $e_2$   
Frequency ( $\text{cm}^{-1}$ ): 2,116 1,976 2,046 1,980 2,014 2,018 1,947

\* The asterisk is used to distinguish the higher of two fundamentals in the same symmetry class.

The twelve 'infra-red-allowed' binary combinations of these fundamentals are as follows:

- $(a_1 + b_2) (B_2)$ . Four separate bands.
- $(a_1 + e_1) (E_1)$ . Two separate bands.
- $(e_2 + b_2) (E_1)$ . Two separate bands.
- $(e_2 + e_1) (B_1 + B_2 + E_2)$
- $(e_2 + e_1) (E_1 + E_2)$
- $(2e_2) (A_1 + B_1 + B_2)$
- $(e_2 + e_2) (E_1 + E_2)$

Seven principal peaks are observed in the 4,000  $\text{cm}^{-1}$  region for both manganese and rhenium carbonyls. The analysis shows that there is considerable overlap of the twelve combinations. Assignment of the spectra has been carried out using: (1) intensity relationships; (2) comparison with related compounds such as  $\text{Mn}(\text{CO})_5\text{Br}$  and  $[\text{Et}_3\text{PMn}(\text{CO})_4]_2$ , the latter compound having the same geometrical structure<sup>6</sup> as manganese carbonyl with the two axial CO groups replaced by  $\text{Et}_3\text{P}$ ; (3) a method of elimination based on internal consistency. Twenty-four possible assignments were tested and only two appeared to be satisfactory. The Raman spectrum of rhenium carbonyl gives complete confirmation of the assignment of the two  $a_1$  modes. The other strong Raman line, at 2,027  $\text{cm}^{-1}$ , must be either  $e_2$  or  $e_1$ , but on the evidence available it is impossible to distinguish between them. However, the form of the equations relating frequencies to a Cotton-Kraihanzel force field<sup>7</sup> indicates that the frequency of the  $e_2$  vibration should be much less than that of the  $e_1$ . For this reason we favour the assignments given in Tables 1-3. We cannot at present explain the weak Raman line at 2,090  $\text{cm}^{-1}$ .

In addition to  $\text{Mn}_2(\text{CO})_{10}$ ,  $\text{Co}_2(\text{CO})_{10}$  and  $\text{Re}_2(\text{CO})_{10}$ , Flitcroft *et al.* have discussed the infra-red active fundamentals of the mixed carbonyl,  $(\text{CO})_4\text{Mn}_2\text{Re}(\text{CO})_6$ . This compound probably has  $O_h$  symmetry and may be expected to show more bands in the infra-red spectrum than the others. In  $O_h$  symmetry  $a_1$  and  $e_g$  modes are infra-red active, and by considering the correlation between representations of groups  $O_h$  and  $D_{4h}$  and by assuming that the general form of the normal modes is similar in homo- and hetero-nuclear carbonyls, it would be anticipated that the three fundamentals corresponding to  $a_1$  and  $e_g$  in  $D_{4h}$  symmetry should become infra-red active. The  $b_2$  and  $e_1$  modes should not change their appearance. The spectrum of  $(\text{CO})_4\text{Mn}_2\text{Re}(\text{CO})_6$  shows three strong bands similar to the other compounds, together with six weaker bands, given as 1945 ( $J$ ), 1992 ( $H$ ),

1998 ( $O$ ), 2031 ( $G$ ), 2044 ( $F$ ), and 2124  $\text{cm}^{-1}$  ( $E$ ). The same letters are used for identification by us.

Flitcroft *et al.* suggest, very tentatively, that band  $E$  may be a binary combination of the  $a_1$  C—O stretching fundamental at 2,054  $\text{cm}^{-1}$  with the Mn-Re stretching vibration. However, we have the following reasons for believing that this band is, in fact, an  $a_1$  fundamental of  $(\text{CO})_4\text{Mn}_2\text{Re}(\text{CO})_6$ , which is infra-red active in  $O_h$  symmetry:

(i) As we have shown, both  $\text{Mn}_2(\text{CO})_{10}$  and  $\text{Re}_2(\text{CO})_{10}$  have infra-red inactive  $a_1$  fundamentals at about 2,120  $\text{cm}^{-1}$ .

(ii) A combination of  $[a_1(2054) + a_1(M'-M)]$  in a molecule of  $O_h$  symmetry corresponds to a combination  $[b_2 + a_1(M_1-M)]$  in a  $D_{4h}$  system which would be permitted in the infra-red. No such frequency can be found.

(iii) The assignment of Flitcroft *et al.* yields a Re-Mn stretching frequency of 70  $\text{cm}^{-1}$ . However, we attribute the strong polarized Raman line in  $\text{Re}_2(\text{CO})_{10}$  at 128  $\text{cm}^{-1}$  to Re-Re stretching, assuming an effective rhenium mass equal to the atomic weight, this corresponds to a force constant of 0.9  $\text{md}/\text{A}$ . With the same force constant, we calculate the metal-metal stretching frequencies in the related compounds as follows: Mn-Re 190  $\text{cm}^{-1}$ , Mn-Mn 236  $\text{cm}^{-1}$ , Re-Re 176  $\text{cm}^{-1}$ .

(iv) The weakness of the band  $E$  in the infra-red is consistent with the small dipole change expected for an  $a_1$  vibration of this sort.

Discussion of the other weak bands reported by Flitcroft *et al.* in all the compounds which they investigated cannot be included here in any detail, but it seems to us probable that band  $O$ , which occurs in all their spectra, is due to the  $e_1$  vibration of molecules with a  $^{13}\text{CO}$  group in a radial position. In  $(\text{CO})_4\text{Mn}_2\text{Re}(\text{CO})_6$ , assignment of band  $H$  to the expected  $a_1$  vibration is in good agreement with the lower  $a_1$  frequencies which we find and band  $J$  may well be the  $e_g$  mode corresponding to  $e_2$  in the homonuclear carbonyls. However, it is at least equally likely that band  $J$  is a  $^{13}\text{CO}$  satellite of the frequency at 1,978  $\text{cm}^{-1}$ , as suggested by Flitcroft *et al.*

There are several features of the assigned fundamentals of manganese and rhenium carbonyls which are worthy of mention. The fundamentals,  $a_1$ \*, have very high values. Qualitatively there seem to be two reasons for this, which reinforce each other. Coupling between different CO groups on one metal atom generally has the effect of raising the frequencies of those vibrations in which the C—O groups stretch in phase. This effect raises both  $a_1$ \* and  $b_2$ \* frequencies. It may be seen from Fig. 2 that in both these modes the five C—O groups on one metal atom

Fig. 2. The forms of the C—O stretching vibrations for a molecule,  $\text{M}_2(\text{CO})_{10}$ , of  $D_{4h}$  symmetry

oscillate with the same phase. Both valence bond theory and molecular orbital theory, however, predict that coupling between O—O groups on adjacent metal atoms would result in a lowering of the in-phase frequencies. In terms of potential energy functions this statement means that the relevant interaction force constants should be negative. Thus it would be predicted that the  $a_1^*$  frequency should be less than  $b_1^*$ . It appears to us that the  $a_1^*$  value is abnormally high because of steric repulsions between the radial OO groups on different metal atoms; these repulsions are most effective when neighbouring OO groups on the two metal atoms stretch in phase, which occurs to the maximum extent in the  $a_1^*$  mode and to the minimum extent in the  $b_1^*$  mode. This explanation can also account for the  $a_1$  frequency being so much higher than the  $a_2$ . These ideas are only qualitative, but we intend to make force constant calculations based on the model suggested by Kraihanzel and Cotton<sup>8</sup>. This model has been used by several workers<sup>9-11</sup>, but has never been fully tested owing to insufficient data.

From these examples, it will be apparent that the utility of measurements in the near infra-red region is of

considerable importance in both the assignment of infra-red active modes and in elucidation of infra-red inactive modes, particularly for complexes where Raman data are difficult to obtain.

## SEPARATION OF LIQUID MIXTURES BY NON-FOAMING BUBBLE FRACTIONATION

By DENNIS C. DORMAN and PROF. ROBERT LEMLICH

Department of Chemical Engineering, University of Cincinnati, Cincinnati, Ohio

OVER the past few years there has been increased interest in the technique of partially separating (concentrating) the components of a liquid mixture by means of foam fractionation. Studies reported include those of our own group<sup>1-4</sup>, as well as those of a number of other investigators<sup>5</sup> including one investigation which appeared recently in *Nature*<sup>6</sup>.

Foam fractionation is based on the preferential adsorption of a solute at the interface of bubbles which are usually formed by deliberately bubbling a gas through a liquid mixture. These bubbles rise, forming a foam which carries the solute off overhead, thus effecting a partial separation of components. Unfortunately, by its very nature, use of the technique is limited to systems which will in fact foam. Accordingly, the present investigation was initiated to examine the feasibility of using a 'foamless foam column'; that is, just a vertically elongated pool of liquid. So far as we are aware, this has been a virtually neglected area of study.

The simple device used is shown in Fig. 1a. It is called a 'bubble column' in contradistinction to a foam column. In the work recorded here it was a vertical glass tube filled to a convenient height with a very dilute aqueous solution of a surface-active agent, namely, technical monobutyl diphenyl sodium monosulphonate. Nitrogen gas (which was first thoroughly humidified to eliminate subsequent evaporation) was bubbled up through the liquid in the column. The objective was to see whether a significant concentration gradient would occur in the column despite the fact the solution was too dilute to foam.

After bubbling for several hours at room temperature, samples were withdrawn from the top and bottom of the column and analysed for solute spectrophotometrically by the standard methylene blue test<sup>7</sup>. A number of runs were conducted. For initial charge concentrations of several parts per million, the concentration at the top was as much as quadruple that at the bottom. Such marked separation shows that, even at concentrations below the foaming threshold, the rising bubbles were quite effective in adsorbing solute at their surfaces and carrying

it to the top of the column. (Bubble fractionation is based on surface adsorption of non-volatile solute and should not be confused with the familiar but quite different operation of desorption which involves diffusion of volatile solute into the bubble interior.) This transport establishes the concentration gradient within the column.

Of course, the operation has its internal limitations. The rising bubbles drag lean liquid from the bottom up to the top. Rich liquid from the top then flows down to the bottom as replacement. The mixing action of this circulation limits the separation attainable.

With bubble sizes in the narrow range of 0.36–0.38 cm diameter, varying the frequency from 120 to 250 bubbles per min was of comparatively little effect. This accords with the aforementioned limitation. Increasing the bubble

Fig. 1. Bubble fractionation apparatus (not to scale). a, Batchwise operation as used here; b, projected flow operation; c, projected application to low-threshold foam fractionation.

frequency increases the undesirable mixing as well as the desirable adsorbing surface.

Fig. 2 and Fig. 3 show the effects of several independent variables on the separation ratio (which is defined as the ratio of the concentration at the top of the column to that at the bottom of the column). The degree of separation increased with the height of the liquid column and with the charge concentration, but decreased with the column diameter. This last would seem to result from a wall effect which is diminished at larger diameters, thus allowing the aforementioned undesirable circulation to proceed with less hindrance.

Fig. 2. Effect of column dimensions on the degree of bubble fractionation for a charge concentration of 3.1 parts per million

The experiments performed here were in batch. However, with sufficient hold-up (liquid residence time) it should be possible to operate continuously as shown in

Fig. 3. Effect of charge concentration on the degree of bubble fractionation in a column of 2.5 cm diameter and 102 cm height

Fig. 1b. Finally, for a solution the concentration of which is only slightly below the foaming threshold, it should be possible to enrich the top of the liquid sufficiently by bubble fractionation so that foam fractionation could be used above it. This is illustrated in Fig. 1c.

## LOWER OLIGOCENE BIRD-TRACKS FROM NORTHERN SPAIN

By DR. J. F. M. de RAAF

Kon/Shell Exploratie en Productie Laboratorium, Rijswijk

AND

DR. C. BEETS and G. KORTENBOUT van der SLUIJS

Rijksmuseum van Geologie en Mineralogie, Leiden, The Netherlands

IN the course of a preliminary sedimentological investigation of a Lower Oligocene formation outcropping in the provinces of Navarra and Zaragoza, Spain, one of us (de R.) discovered bird-tracks. Some time afterwards his co-authors collected more material from the same locality and, by proceeding along the strike, sampled scores of other bird-tracks and natural casts. The collected material, now kept in the Rijksmuseum van Geologie en Mineralogie, Leiden, derives from an outcrop area some 40 km long, starting from the westerly wedge-out of the fossiliferous formation, via the Liedena area where bird-tracks had been first observed by Mangin<sup>1</sup>, to the east (Bailo-Salinas de Jaca area), where it is increasingly better developed, but where tracks are apparently lacking.

The lowermost part of the continuous Oligocene section discussed here contains in the Liedena area lagoonal gypsiferous deposits, which are a few tens of metres thick. They are overlain by Mangin's 'grès à ripplemarks' and together with the latter form a complex almost 100 m thick.

With respect to the mode of deposition, two types of sandstone can be distinguished in this sequence, namely, graded sandstones with bases channelling into the beds below and others the deposition of which evidently did not alter the original upper surface features of the underlying bed. As regards sole markings, flute casts are restricted to the first type, casts of bird-tracks and lower surface ripple-marks to the second type.

These sediments form the base of the post-orogenic fill of the Ebro basin and should not be considered a 'flysch', as Mangin contends, in spite of their rhythmic aspect and local grading<sup>2</sup>. In slightly more detail, this type of sequence is as follows: The basal part of the Oligocene in the region with bird-tracks outlined here generally consists of red and grey to greenish calcareous shales with thin intercalations of siltstone. Both the shales and siltstones contain a certain amount of gypsum. This sequence grades upwards into a much more arenaceous succession with scores of beds with bird-tracks (Fig. 1). Generally, it consists of alternating rather fine to medium-grained sandstones, siltstones and calcareous to silty shales. There would appear to be a predominance of non-graded beds, particularly as regards the thinly bedded fine-grained units. Sandstones containing irregular silty to pelitic trends are not infrequent. Several thin beds show evidence of slumping. Many of the sandstones and siltstones display ripple-marks on their lower or upper surfaces. There are some apparently symmetrical ripple-marks, which are generally thought to be due to wave action.

The best examples of grading (ref. 2, p. 195) were found in the thickest sandstone beds (thickness about 1 m or more). On the sole of the graded units flute casts and groove casts are occasionally present. Mudflakes were observed near the erosional base of several of these beds.

Towards the top of the arenaceous succession the sequence becomes generally finer-grained and consists predominantly of finely grained thin-bedded sandstones and siltstones alternating with calcareous pelites. The lower surfaces of the arenaceous beds are here particularly rich in very delicate sole markings connected with bioturbation, the presence of pseudomorphs after salt crystals, striations, etc. It was interesting to find coprolites of the same nature as those described from the Rotliegendes by Reineck<sup>3</sup> as *Planolites rugulosus* n.sp., stemming from a similar environment. Bird-tracks, both on sandstones or siltstones (occasionally on ripple-marked surfaces or

associated with salt pseudomorphs) and on shales (evidenced as natural casts on the sole of overlying arenaceous beds), occur in the entire arenaceous succession, although more frequently in its lower part.

Finally, there are mud cracks and also, not infrequently, rain imprints mainly on shaly, silty beds throughout the sequence.

Eastwards, the whole arenaceous succession thickens and red colours become predominant. Burrows, presumably made by crabs, and at places passing from a sandstone through a thick shale bed into the underlying sandstone, finally occur in such abundance that the observed concurrent lack of bird-tracks may be confidently attributed to their being obliterated by intensive burrowing activities. As to the environment of deposition of the sediments discussed here, our observations do not seem to tally with opinions often expressed regarding depth of formation. Thus, the individual graded units encountered in the various sections traversed are often quite similar to deep-water deposits in other formations, at least in outward appearance. However, there can be little doubt that the sequence described here was deposited in an environment with shallow or negligible aqueous cover, in a coastal belt with temporary and local evaporitic conditions. In such an environment, minor streamfloods originating in a hinterland with little topographic relief after cloud bursts may be the depositing agent of the generally rather finely grained graded beds encountered.

It finally remains to consider the extraordinary, and often beautiful, preservation of a truly amazing abundance of bird-tracks in an area of the order indicated. It is hard to see how tracks abounding in all directions so repeatedly could be preserved at all with such regularity without invoking aeolian action. Only thus can we envisage the much-repeated mechanism of quick burial and most successful preservation of the tracks after their imprint in exposed wet arenaceous to clayey sediments, first with wind-blown salt and sand derived from drying flats and only later by more sediment transported by water.

Fig. 1

However, observations on the subject are, we believe, still largely lacking and the matter would require some considerable further study.

In this article no attempt will be made to describe the fossil tracks in any detail. Again, there seems, at this stage, little point in figuring all the various types of tracks discovered. It may be stated that the tracks appear to have been made largely by semi-aquatic birds on slightly emergent mud and sand or salt flats, probably subject not only to repeated inundations but also to repeated drying with associated aeolian transport. Most of the tracks were apparently made by a limited number of species which flocked together in a favoured environment and did so for a very long time. The various fossil-track assemblages, when fully studied, may well give us an interesting insight into the animal life of the period concerned in a fairly wide region in northern Spain.

Fig. 1, showing one of the largest slabs of siltstone collected, is given here as an example of the more interesting assemblages (imprints) discovered. As in most instances observed by us, the majority of tracks were evidently made by small wading birds, and some of these, at least, show affinity to tracks made by sand-pipers, snipe-like birds, and other small birds, or by gulls. More spectacular are the large tracks, often of astounding

clarity of impression, of a large web-footed bird. A preliminary investigation suggests that we may well have to look among the heron types of wading birds, more particularly the stork family (Ciconiidae), for the nearest relatives of these web-footed birds. It is not surprising that the tracks should have a 'modern' appearance, for most of the bird families now living had already evolved by Upper Eocene time.

So far, bird-tracks have been but rarely reported from northern Spain<sup>1,4</sup> and those reported by Hernandez<sup>4</sup>, although likewise of an Oligocene age, are quite unlike any discovered by us. Recent literature on the subject of bird-tracks (compare Abel<sup>5</sup>) includes interesting finds in Poland, the Rumanian Carpathians<sup>6</sup>, and the Uinta Basin (Eocene), Utah, United States<sup>7</sup>.

## ENVIRONMENTAL DETERMINATION OF INSULAR VARIATION IN BIRD SPECIES ABUNDANCE IN THE GULF OF GUINEA

By PROF. TERRELL H. HAMILTON† and NEAL E. ARMSTRONG

Department of Zoology, University of Texas, Austin, Texas

FIGURE 1 illustrates for the avifaunas of the four islands in the Gulf of Guinea off West-Equatorial Africa the well-known species-area and species-isolation curves. The first is positive, the latter is negative, and the species numbers vary positively when plotted against maximum elevation of the islands. The data are from Amadon<sup>1</sup> and indicate that bird species numbers increase with area (slope =  $z = 0.489^*$ ) less rapidly than with decreased distance from the mainland ( $z = -0.866$ ). The question arises: do bird species numbers ( $Y$ ) vary among the islands in a way that  $Y$  depends on several factors (such as area, elevation and isolation) for determination of its value? Here it can be assumed that insular area and elevation are positive indices of ecological diversity and the likelihood of newly arrived dispersers finding vacant or available ecological niches, and that isolation, measured as each island's distance from the African mainland, makes negative the chances for dispersers to reach given islands<sup>2,3</sup>.

Multiple regression analysis provides one test for the problem, and among others two models or estimating equations are convenient and standard:

$$\hat{Y} = a_{Y.12} + b_{Y.1}X_1 + b_{Y.2}X_2 \quad (\text{Model I}) \quad (1)$$

and

$$\log \hat{Y} = \log a_{Y.12} + b_{Y.1} \log X_1 + b_{Y.2} \log X_2 \quad (\text{Model II}) \quad (2)$$

Here,  $b$  is a pure number, being the ratio of increase in  $Y$  (dependent variable) with that of  $X$  (independent variable), independent of other  $X$ s. The intercept value or constant ( $a$ ) is the value of  $Y$  or  $\log Y$  when the  $X$ s or  $\log X$ s are zero. The two models derive respectively from the linear and non-linear equations:

$$y = bx, \quad (I) \quad (3)$$

where  $x = x^z$  with  $z = 1$ , and

$$y = bx^z \quad (II) \quad (4)$$

where  $z \neq 1$ .

† Present address: National Institute for Medical Research, Mill Hill, London, N.W.7.

For multiple regression analysis involving four variables (1 dependent, 3 independent), we have found with our computer programme (University of Texas: Tennessee Valley Authority Multiple Regression Comprehensive Analysis) that a minimum of 5 sample items is necessary for consistent calculation of the standard deviations ( $s_y$ ) (ref. 4) of the partial regression coefficients. For a fifth sample we selected the highlands of Mt. Cameroon (13,350 ft.) on the mainland coast of the Gulf. Searle<sup>5</sup> records 67 bird species for the montane forest (lower limit: 5,000 ft.) of this volcano, which is about 22 miles from Fernando Po in the Gulf. If from standard maps we estimate the radius ( $r$ ) of the volcano at 5,000 ft. as 7 miles, and if we assume a right cone with a height ( $h$ ) of 8,350 ft. for the volcano's 'cap' above 5,000 ft., then the new sample's area or curved surface area ( $csa$ ) is 169 sq. miles by the formula  $csa = \pi r \sqrt{r^2 + h^2}$ . Although isolation for

Fig. 1. Bird species-area and species-isolation curves for the four islands in the Gulf of Guinea. To show by closed (●) and open (○) circles their respective positive and negative trends. Closed and open triangles designate respective values for the montane sample of Mt. Cameroon, but these values are not utilized in the calculation matrices for the regression lines. Raw data ( $Y$ , species;  $X_1$ , area;  $X_2$ , elevation,  $X_3$ , isolation) for each island or sample. Annobon (9 bird spp., 6.8 sq. miles, 1,969 ft., 211.2 miles); Principe (20, 48.7, 3,110, 136.7); São Tomé (44, 536.1, 6,640, 174.0); Mt. Cameroon (67, 169, 8,350, 1); and Fernando Po (133, 852.6, 9,350, 19.9)

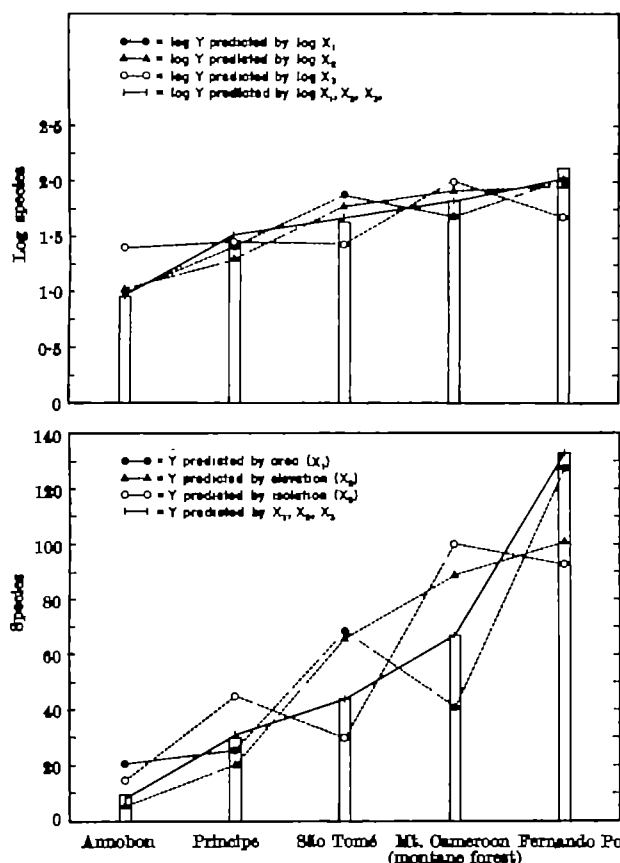

Fig. 2. Predictions by single and multiple regression analyses of the variation in bird species numbers in the Gulf of Guinea. Lower plot, predictions by Model I; upper plot, by Model II. Open bars designate vertically reported numbers of bird species. To show that knowledge of area, elevation, and isolation gives near-perfect prediction of the insular variation in bird species numbers. Standard errors of the estimate for  $\hat{Y}$  and  $\log \hat{Y}$  predicted by the three variables (equations (3) and (4)) are 1.6 species and 0.068 log species.

this continental sample should be zero or negligible, it can be assigned a token value of 1 mile. This avoids for Model II the problem of working with the common logarithm of zero, or minus infinity. That Amadon<sup>4</sup>, Searle<sup>5</sup>, Moreau<sup>6</sup>, and others have discussed the strong geological and avifaunal affinities between this volcano and its insular relatives nearby in the Gulf is considered justification for our use of this additional sample.

Table 1 summarizes computer results of an examination by the models of the regression of  $Y$  on the  $X$ s and of  $\log Y$  on the  $\log X$ s, and we note that a secondary aim of this report is to check the feasibility and appropriateness of a multiple regression investigation of a biological system with few sample items. Goodness of fit for regression of  $Y$  or  $\log Y$  on the  $X$ s or  $\log X$ s is estimated by the size of  $R^2$  or the coefficient of multiple determination ( $= \Sigma \hat{y}^2 / \Sigma y^2$ ) (ref. 4). All single and partial regression coefficients are tested by Student's  $t$ -distribution ( $t_0 = b/s_b$ ), and may be considered insignificant unless designated by an asterisk\* (significant:  $0.05 > P > 0.01$ ) or asterisks\*\* (highly significant:  $P < 0.01$ ).

Preston<sup>7</sup> and MacArthur and Wilson<sup>8</sup> have suggested the respective indexing of isolation by the reciprocal and square of the distance, and Hamilton *et al.*<sup>9</sup> have used the linear (that is, arithmetic or untransformed) value of distance. For  $Y$ , but not  $\log Y$ , we have tested the reciprocal and square transformation ( $X_3$ ,  $X_7$ ) of the isolation or distance measurement ( $X_1$ ,  $X_2$ ), along with the squares ( $X_4$ ,  $X_5$ ) or area ( $X_1$ ) and elevation ( $X_2$ ). The  $X$ s are used in single and multiple regression for two and three independent variables with 'overlapping' not allowed. For example, for predictions with area, elevation,

and isolation, only one measurement or transformation of each variable ( $[X_1$  or  $X_4] \cdot [X_2$  or  $X_5] \cdot [X_3$  or  $X_6$  or  $X_7]$ ) is used in any multiple regression.

The results summarized in Table 1 (cf. values for  $R^2$ ) are good in most cases, but the better predictions are by the linear measurements of  $X_1$ ,  $X_2$ , and  $X_3$ , or their logarithmic counterparts. For isolation, however, the square of the distance is clearly superior to the reciprocal in predicting  $Y$ —a point of some value in speculations on the shape of the dispersal curve for bird species crossing water-gaps (cf. Hamilton and Rubimoff<sup>9</sup>).

Either by Model I or II it is obvious (Fig. 2) that an almost perfect prediction ( $R^2 = 0.99$ – $1.00$ ) of Amadon's and Searle's data for variation in bird species numbers in the Gulf of Guinea can be obtained by use of three measurements of their insular or sample environment: area, elevation, and isolation. For predictions noted in Fig. 2, the multiple regression equations for 3  $X$ s are:

$$\hat{Y} = 78.180 + 0.110 * (\text{area}) - 0.004 (\text{elevation}) - 0.302 * (\text{isolation}) \quad (\text{I}) \quad (5)$$

and

$$\log \hat{Y} = 9.712 + 1.225 (\log \text{area}) - 2.702 (\log \text{elevation}) - 0.391 (\log \text{isolation}) \quad (\text{II}) \quad (6)$$

In equation (5)  $\Sigma y^2$  is 9077.2, and the sum of squares attributable to regression ( $\Sigma \hat{y}^2$ ) is 9074.7. All parts of equation (6) are insignificant, and its intercept value ( $a$ ) is extraordinarily high, being approximately  $10^{10}$  bird species when the  $\log X$ s are projected to zero. This is of mathematical rather than of biological significance, and stems from the inclusion in the equation of  $\log$  elevation, with which  $\log Y$  in this instance varies negatively, and thus increases (1) as elevation approaches zero (see (3) below).

The better multiple regressions with two independent variables occur by the following equations:

$$\hat{Y} = 54.150 + 0.094 ** (\text{area}) - 0.231 * (\text{isolation}) \quad (\text{I}) \quad (7)$$

and

$$\log \hat{Y} = 0.880 + 0.444 * (\log \text{area}) - 0.117 (\log \text{isolation}) \quad (\text{II}) \quad (8)$$

Standard errors of the estimate ( $s_y$ ) for  $\hat{Y}$  and  $\log \hat{Y}$  predicted by the two equations are respectively 6.1 species and 0.134 log species. With elevation ( $X_2$ ) withdrawn from the calculation matrices, the models account here

Table 1. INSULAR VARIATION IN NUMBER OF BIRD SPECIES IN THE GULF OF GUINEA

Coefficients of determination ( $r^2$ ) and multiple determination ( $R^2$ ) for regression on three environmental factors and their transformations

† Under Models I and II are listed the respective values for  $R^2$  ( $= r^2$  for single variables) for the arithmetic-to-arithmetic and logarithmic-logarithmic regressions.  $R^2$  or  $r^2 = \Sigma \hat{y}^2 / \Sigma y^2$  = fraction of variation accounted for by regression of the dependent variable on the independent variable(s). Degrees of freedom with  $n = 5$ : for 1  $X$ , 3; for 2  $X$ s, 2; for 3  $X$ s, 1. Note: no attempt is made here to evaluate relative goodness of fit between the models, or between the various variable combinations where each set has a high  $R^2$  value.

Table 2. INSULAR VARIATION IN NUMBER OF BIRD SPECIES IN THE GULF OF GUINEA

Variation and its sources†	Analysis and partitioning of the variance Degrees of freedom	Sum of squares	Mean squares
Bird species sample Nos.	4	$\Sigma y^2 = 9,077.2$	
Environmental variation	2	$\Sigma y^2_{12} = 9,002.1$	4,501.1**
Unexplained variation	2	$\Sigma y^2_{12} = 75.1$	37.5
		$F = 4,501.1/37.5 = 108; P = < 0.01$	
Area and isolation	2	$\Sigma y^2_{12} = 9,002.1$	
Area alone	1	$\Sigma y^2_{12} = 7,622.7$	
Isolation minus area	1	1,379.4	1,379.4**
Area and isolation	2	$\Sigma y^2_{12} = 9,002.1$	
Isolation alone	1	$\Sigma y^2_{12} = 5,878.2$	
Area minus isolation	1	3,123.9	3,123.9**
Unexplained variation (error)	2	75.1	37.5

Interpretation of analysis: (i) by test of null hypothesis, no significant variation in bird species numbers is unaccounted for by variation in area and isolation; (ii) variations in area and isolation contribute independently of one another to separate, significant components of bird species variance.

† Variation in bird species numbers ( $Y$ ) =  $\Sigma Y^2 - (\Sigma Y)^2/n = \Sigma y^2$ ; environmental variation =  $\Sigma y^2_{12}$  = sums of squares accounted for by regression of  $Y$  on  $X_1$  (area) and  $X_2$  (isolation).  
 $F$  = Fisher's<sup>12</sup> and Snedecor's<sup>11</sup> variance ratio.

respectively for 99 and 95 per cent of the variation in  $Y$  and log  $Y$ . Note also the marked decrease in the intercept value of equation (8) (cf. equation (6)). By comparing values for  $R^2$  in Table 1 for predictions by the three possible pairings of the  $X$ s or log  $X$ s, one readily sees that area and isolation are the more important contributors to bird species' variance by either Model I or Model II. A 'quick and dirty' test of significance for  $R^2$  values in Table 1 is by evaluating their square roots ( $= r$  or  $R$  = coefficient of correlation or multiple correlation) against R. A. Fisher's significance table for correlation coefficients<sup>13</sup>. Thus with 3, 2 or 1 degree(s) of freedom, any  $r^2$  or  $R^2$  value in Table 1 must be 0.771, 0.903 or 0.994 to attain at least a 0.05\* level of significance.

Analyses and partitioning of the variance<sup>4</sup> of  $Y$  and log  $Y$  support the conclusion from the comparison of  $R^2$  data (Table 1) that area and isolation are the important 'pushers' of bird species' numbers. For equation (7) (Model I), Table 2 presents such an examination of the variance, and shows by results of  $F$ -tests: (i) that no significant variation in  $Y$  remains unaccounted for by regression on area and isolation ( $\Sigma y^2 = 9,077.2$ ;  $\Sigma y^2_{12} = 9,002.1$ ); (ii) that each variable accounts separately for a significant component of  $Y$  variance. As the small sample size ( $n = 5$ ) suggests a probable departure of  $r$  from normality, we have tested the correlation and multiple correlation values by R. A. Fisher's normalizing transformation of  $r$  to  $z_r$ , where  $z_r = 0.5 [\log_e (1 + r) - \log_e (1 - r)]$ . In an important instance, a value of 0.998 for  $R_{12}$  (cf. Table 2 where  $R^2_{12}$  is 0.991) is significant\*\* both by  $t$ -test and by  $z_r$ -test, with  $z_r$  being 2.394 as determined (see ref. 9, 280) by the difference between 0.5 log<sub>e</sub> for mean square of  $\Sigma y^2_{12}$  and such for  $\Sigma y^2_{12}$ .

**Concluding discussion.** (1) Multiple regression analysis reveals that insular area, isolation, and elevation may be respectively considered as major, minor, and trivial contributors to variance for bird species numbers of isolates and a sample in the Gulf of Guinea. Together the variables give near-perfect prediction (Fig. 2) of Amadon's<sup>1</sup> and Searle's<sup>8</sup> data. That coefficients of multiple determination ( $R^2$ ) are greater than those of single determination ( $r^2$ ) (Table 1) suggests strongly that insular variation in bird species abundance is determined by several factors—a principle rather obvious, but rarely demonstrated. In the Gulf of Guinea, then it appears that two factors 'working' in opposition to one another interact to 'fix' insular avifaunal size: one, area presumably reflecting environmental opportunity or ecological diversity; and the other, isolation.

(2) Recently, interest has been expressed in the value of  $s$  or the slope of the regression line ( $b$  by our Model II) for log species regressed on log area<sup>1,7,8</sup>. In the present work,

the first-order, species-area curve ( $z_{y1}$ ) is 0.50\* for the five sample items. When 'corrected' in multiple regression,  $z_{y1.12}$  becomes 1.22\*, and when 'recorrected' by removal of log  $X_2$  (trivial contributor to variance of log  $Y$ ) the value (now  $z_{y1.2}$ ) becomes 0.44\*. This is larger than such exponential values reported for the three other, more isolated archipelagos, the avifaunas of which have been analysed correspondingly (West Indies, 0.24\*\*, East Indies, 0.28\*\*, and East-Central Pacific, 0.30\*\*) (ref. 2).

Preston in his canonical theory<sup>7</sup> for species abundance considers  $z$  to become smaller as oceanic isolates become continental samples. MacArthur and Wilson, in their equilibrium theory<sup>8</sup>, proceed from population-turnover theory to statistical aspects of species numbers distribution and conclude that  $z$  becomes larger as islands or sets of islands become more isolated. In this instance the different theories of the workers cited predict the same (i) response, namely, that  $z$  becomes smaller with decreased isolation. Although the small sample of 5 prevents our conclusion from being taken seriously, the bird species-area curve for the Gulf of Guinea is the opposite of what would be expected by either the canonical or equilibrium theory. That is, it is larger, not smaller, for a set of islands next to a continent, the equatorial avifauna of which probably has a relative ancient history. It should be noted, turning the discussion coin to its other side, that the findings of Hamilton and co-workers<sup>3</sup> for 'corrected' species-area curves for the two Pacific and West Indian avifaunas offer support for both theories. The values listed here at once average 0.273 (Preston's theoretical  $z$  value: 0.270) and show an increase in value (0.24 → 0.28 → 0.30) when listed in increasing order of their archipelago's oceanic isolation from continental or zoogeographic source regions (MacArthur and Wilson's conclusion).

(3) Finally, the negative partial regression coefficient for species-elevation variation by both models (equations (3) and (4)) hints at the minimum of decrease in bird species numbers when such variation is independent of area and isolation. This is a non-obvious finding, for the regression of  $Y$  on  $X_3$  only is positive ( $b_{y3} = 0.013^*$ ). Since the contribution of elevation ( $X_3$ ) to  $\Sigma y^2$  is trivial and insignificant, the finding may either be an insignificant variability due to the small value of  $n$  or be a result of correlation or confounding between the  $X$ s themselves (but  $r_{12}$  or  $r_{23}$  is each less than 0.80; see ref. 4); or the finding may be an indication of a reality which would occur if  $n$  were larger! Having noted these alternatives, we propose to consider the latter, improbable (admittedly) possibility for heuristic purposes only:

Imagine a circular, sea-level island. To increase in elevation without increasing in surface area, a reduction in sea-level circumference must be attendant to the rise of an elevation peak. The problem resolves to the question of how a shift in space from the lowlands to the highlands—without insular change in total surface area or isolation—might result in fewer species?

Writing in the vein of theorists and systems-makers, we offer three of various possible answers to the questions posed: (i) Bird species may immigrate into new areas less rapidly than they become extinct by the loss of equal area. (ii) Bird species restricted or adapted to highland zones may have a higher extinction rate than their lowland counterparts. (iii) Suggested by R. H. MacArthur and possibly related to (ii). Insular bird species adapted to montane habitats may have a lower immigration rate than lowland species as a result of the greater distances necessary for their inter-island or continent-to-island dispersal. Since there is less space for species in the highlands than in the lowlands, suggestion (ii) finds support in—indeed, it may be another manifestation of—the observation<sup>14</sup> that species of small islands or continental isolates become extinct more rapidly than species in the larger situations.

Making an analogy with decrease in number of species per unit area on passing from tropical to temperate to

arctic latitudes, we thus predict that when bird species-sample area studies are carried out at various elevations within these and perhaps other islands the species-elevation curve for intra-island situations will in the main be negative.

## GEOLOGY OF RÉUNION ISLAND, INDIAN OCEAN

By DR. B. G. J. UPTON

Department of Geology, University of Edinburgh

AND

DR. W. J. WADSWORTH

Department of Geology, University of Manchester

IN recent years petrologists have devoted considerable attention to the volcanic islands of the oceans, and the Hawaiian archipelago, in particular, has been accepted as a classic area for the study of basalts<sup>1-3</sup>. From a review of the literature on oceanic basalt islands it became apparent that Réunion in the Indian Ocean is one of the few other oceanic islands offering a volcanic sequence comparable in thickness and variety to those of the larger Hawaiian islands, and that it would be profitable to make a detailed study of its petrology. The following account presents the preliminary results of this work, based on two periods of field-work in July and August in 1963 and 1964.

Réunion is situated at 55° 30' E. and 21° S. on the southern extremity of the Mascarene ridge in the western Indian Ocean. The island is ovoid in plan with a long axis directed N.W.-S.E. and an area of 2,512 km<sup>2</sup>. It emerges from depths in excess of 4,000 m to culminate in two volcanic summits: Piton de la Fournaise, in the south-east, is an active basalt cone reaching 2,631 m above sea-level, while Piton des Neiges in the north-west, despite its long extinction and severe erosion, still attains a height of 3,069 m. The diameter of the whole volcanic complex at the -4,000-m contour is c. 190 km and the average gradient from this depth is 4.5°.

Piton de la Fournaise has been described in considerable detail by a number of investigators, among whom Lacroix<sup>4,5</sup> is outstanding. But the older massif of Piton des Neiges has received much less attention<sup>6,7</sup>. Piton des Neiges is apparently unique in its combination of extreme dissection and variety of rock types. Not only are the youngest lavas and ashes largely preserved but, as a result of amphitheatre-headed valley erosion on a prodigious scale, relatively ancient suites of effusive and intrusive rock, ranging from ultrabasic to acid in composition, are displayed for examination deep within the core of the original volcano. The lavas fall naturally into two groups generally separated by a well-defined erosional discontinuity; the younger Differentiated Series consists mainly of hawaiite, mugearite and feldsparphyric basalt flows with thick intercalated pyroclastic deposits, and the older Oceanite Series consists mainly of olivine-rich basalt flows, which tend to be thinner, to have lower dips and to be associated with much less interbedded pyroclastic material than the lavas of the Differentiated Series. Ultrabasic inclusions occur sporadically among the flows of the Oceanite Series.

The lowest structural levels of the volcano are encountered in the floors of the three great erosional cirques

which surround the summit of Piton des Neiges. Here, the lavas of the Oceanite Series are underlain by a massive accumulation of poorly bedded agglomeratic material, at least 1,000 m thick, composed entirely of fragments of olivine-rich basalts, identical in type to the overlying lavas. The total thickness and lateral extent of this Cirque Agglomerate is not known, because only the top part of the pile is seen and it is not clear whether it accumulated within a caldera or over the flanks of the volcano during its earlier history.

Deep erosion to the north-east of the summit in the Salazie cirque has revealed zones of intense mylonitization in the Oceanite Series. The mylonitization appears to be associated with the occurrence of low-angled thrust-planes dipping towards the volcano centre. At one locality a slice of layered gabbro, tens of metres thick, occurs among the crushed lavas and has itself been partially mylonitized. The Oceanite Series and the Cirque Agglomerate are dissected by dykes, sills and inclined sheets, which become concentrated towards the core of the volcano into intense 'sheet-swarms' where the country rock makes up only a very small percentage of the total outcrop. The earliest members of this hypabyssal suite are ultrabasic sheets, some of which have been observed to cut the layered gabbro. These were succeeded by innumerable basic and intermediate intrusions including at least one strongly differentiated sill. The largest intrusions are massive undulatory sheets of syenite, up to 100 m thick and containing numerous narrow veins of quartz-sandstone-calcite pegmatite. The syenites are among the latest intrusions cutting the Oceanite Series and the Cirque Agglomerate, but are themselves cut by occasional thin basic dykes. No clear pattern of intrusion is discernible among the minor intrusives exposed in the floors and walls of the cirques, but a radial swarm of olivine basalt and oceanite dykes can be recognized within the Oceanite Series on the flanks of the volcano.

At some time before the extrusion of the Differentiated Series and probably before deep dissection of the primitive olivine basalt shield, zeolites were deposited in the vesicles of the lavas forming the central part of the volcano. The zeolitization affects the Cirque Agglomerate wherever it is seen, the inner and lower parts of the Oceanite Series and the great majority of the basic and ultrabasic intrusions. The later intrusions, including the syenites, are not zeolitized and clearly represent a later event probably synchronous with the eruption of the Differentiated Series.

On the northern and western flanks of the mountain the lavas and fragmental rocks of the Differentiated Series were laid down in an apparently conformable sequence with no obvious erosional breaks, and the strata thin very rapidly away from the volcano centre. The surface of the youngest material in these areas has been little modified by erosion since its formation; on the higher ground this surface is composed of moderately consolidated ash a few metres thick. Around the western flank of the volcano the lower slopes are built of apparently youthful, blocky flows of feldsparphyric basalt.

On the eastern flanks of Piton des Neiges the situation is much more complex. This is the side of the volcano which has received most of the precipitation from the east and south-east trade-winds, and here radial stream erosion has been extremely vigorous. During the later evolution of the volcano (at least) it would seem that no sooner was a deep ravine trenched into the mountain-side than it was occupied and obliterated by new flows from the summit crater. Between periods of extrusion new stream valleys were developed on either side of the flows thus channelled by earlier valleys and these, in turn, were filled by lava. The repetitive pattern of events, whereby valleys created by water during periods of comparative quiescence were destroyed by lava during subsequent volcanic activity, has been recognized by Stearns<sup>8</sup> in his work on the Hawaiian volcanoes. The consequences of this erosional bias to the windward or eastern side of Piton des Neiges included faster valley-head migration towards the summit crater with consequent concentration of flows on this side of the mountain, and the development of relatively thick flows as a result of restriction to steep-sided ravines. In other words, in spite of inequality of erosional rates around the mountain, an approximately symmetrical shield profile was maintained.

There is one clearly demonstrable intraformational erosional break within the Differentiated Series on the eastern side and others are strongly suspected. The youngest flows emitted from the summit cone were directed along valleys trenched into earlier members of the Differentiated Series. These distinctive young flows are of intermediate composition and carry phenocrysts of plagioclase, olivine, augite and magnetite. Like the feldsparphyric basalt flows near the west coast, the surface features have been little changed by subsequent erosion. The latest flows and pyroclasts of Piton des Neiges are believed to have been erupted from a relatively steep-sided (15–20°) summit cone the top of which lay approximately 300 m higher than the present summit. Massive and apparently horizontal flows, not accessible but thought to belong to the Differentiated Series, are exposed on the steep eastern side of the summit massif about 1,000 m below the summit itself, and are inferred to be caldera-filling flows. Thus, although there is no evidence whatever of caldera fracturing during the final stages of activity, it seems probable that such structures did exist at least once, during the earlier development of the Differentiated Series.

The most spectacular flows of the Differentiated Series are those forming the south wall of the Salazie cirque; these are very thick (up to 100 m), nearly horizontal units, exhibiting prominent columnar jointing. The accessible members of this group are seen to contain a very high proportion of basalt fragments representing earlier eruptions, in a glassy and flow-banded matrix containing abundant phenocrysts of anorthoclase and sanidine. The evidence suggests that these flows are 'nuée ardente' deposits formed during eruption of magma which was probably similar to that which produced the intrusive sheets of quartz syenite elsewhere, although the high content of included basalt chips precludes an accurate assessment of its composition.

The three great cirques of Piton des Neiges are erosional features which owe their distinctive form to the contrast between the lavas of the Differentiated Series and the

underlying rocks. The Oceanite Series is composed principally of thin vesicular flows separated by scoriaceous horizons and it is therefore relatively susceptible to erosion. This applies even more to the zeolitized parts of the Oceanite Series and to the Cirque Agglomerate. Thus, the older agglomerates and lavas, within a 7-km radius of Piton des Neiges's summit, have relatively little coherence and crumble readily. The overlying Differentiated Series, consisting mainly of tough massive flows of basalt and intermediate rocks, forms a relatively competent cover. Wherever a consequent stream has been initiated on this cover and eroded a gorge sufficiently deep to expose the older series, the process of undercutting, valley widening and deepening, and headward erosion is accelerated and reaches its extreme development when the valley heads penetrate the rotten core of the volcano comprising the zeolitized lavas and pyroclasts. Lateral undercutting and land-sliding become the principal erosional processes and the resulting avalanche deposits spread out as loosely consolidated sheets (shown as 'drift' in Fig. 1) over the valley floors where they are rapidly dissected into a 'bad-land' topography by stream run-off. Cilaos and Salazie, the principal towns within the cirques, are both built upon erosional remnants of great debris deposits of this type. The surfaces of such deposits may weather to form lateritic soils before becoming submerged by further avalanche flows, and hence a crudely bedded appearance results in some sections. Previous writers have not clearly distinguished the crumbling zeolitized lavas and agglomerate (both riddled by minor intrusions) from the superficial avalanche debris and fluvial sediments and have simply described all fragmental material forming the rugged floors of the cirques as 'basaltic detritus'. The development of only three large cirques (with possibly a fourth to the east, now filled with the youngest lavas), rather than a number of amphitheatre-headed valleys, seems to indicate that the first few valleys to penetrate the core proceeded to dominate the situation by relatively rapid lateral extension and 'capture' of the run-off previously feeding the neighbouring valleys.

A number of ancient terraces, composed of fluvial sands and pebble-beds, occur in the river gorges draining out from the cirques. Some of these, through which the streams have trenched deep ravines, are more than 100 m thick. At present, deposition of this sort of material is occurring only in the deltaic fans at the seaward ends of the gorges. It is probable that the older deposits were accumulated in large temporary lakes formed by the ponding up of the rivers behind dams created by massive land-sliding from unstable mountain-sides.

The eruptive histories of Piton des Neiges and Piton de la Fournaise have undoubtedly had considerable overlap, and Réunion must have passed through a stage when it consisted of a relatively steep, explosively active, cone to the north-west, emitting a variegated sequence of products, and a basalt shield volcano to the south-west, producing a rather uniform series of lavas. These basalts, olivine basalts and oceanites are strikingly similar to the older series of Piton des Neiges. In spite of being a highly productive volcano, Piton de la Fournaise is also deeply incised by river gorges. The drainage pattern is partly radial and in part directed by a series of caldera ring-fractures. The latter are closed (convex) towards the west but are open towards the east. It is probable that they have developed as a combination of vertical caldera-collapse (as at Kilauea and other Hawaiian volcanoes) and slumping towards the steep, unsupported, eastern side of the volcano. The modern cone has three intersecting crater-pits at the summit, of which the most easterly is the focus of contemporary activity. The cone is itself enclosed on its southern, western and northern sides by a caldera wall 100–300 m high. Most historic eruptions have occurred within the bounds of this caldera, the flows being predominantly directed towards the east. Prehistoric and historic flows have spilled into some of the

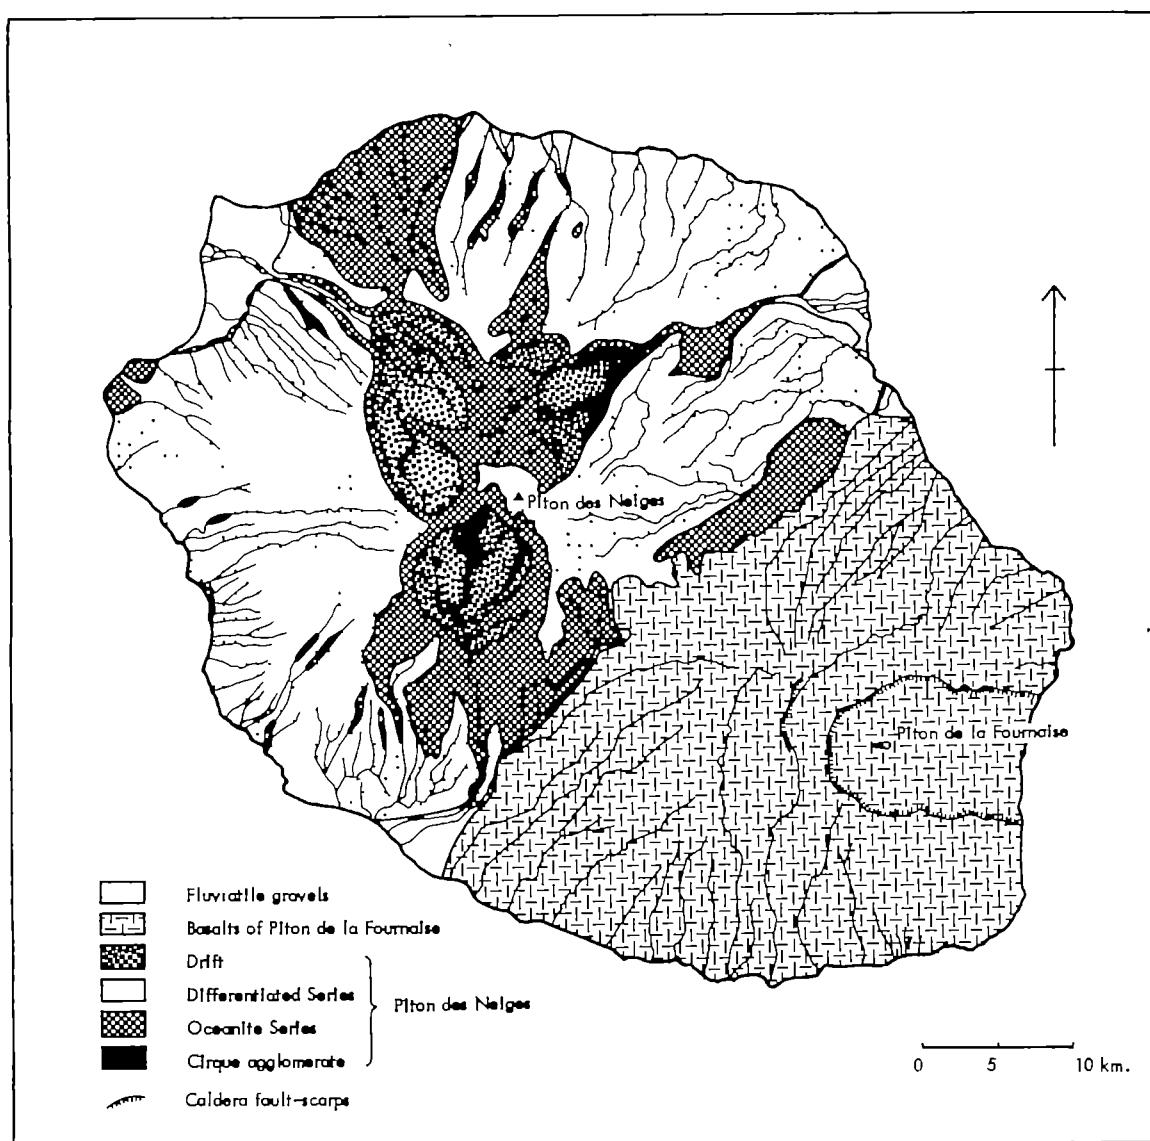

Fig. 1. Simplified geological map of Réunion

great river gorges on the mountain and conspicuous unconformities result. A former deep gorge, excavated by a river flowing north-east at the confluence of the dip slopes of the two volcanoes, has been largely obliterated by prehistoric flows spreading northwards from the summit region of Piton de la Fournaise. These erosional unconformities are, however, not marked by any significant change in lava type. The interpretation of a series of massive, horizontal flows as an ancient caldera-filling suite to the north-west of the modern eruptive centre, consideration of the existing caldera features, and the geology of the island as a whole, lead to the suggestion that there has been a steady overall shift in the centre of activity south-eastwards from Piton des Neiges.

A few small dykes are the only intrusions visible in the caldera walls and gorge sections on Piton de la Fournaise, and there is no suggestion of any zeolitization among the rocks of this volcano. Lacroix<sup>4</sup> has described the occurrence of ultrabasic nodules from Piton de la Fournaise; inclusions are absent from most flows, but locally they are

Fig. 2. Alkali-silica plot for lavas from Réunion and Mauritius. Solid circles, Oceanite Series of Piton des Neiges and basalts of Piton de la Fournaise; open circles, differentiated Series of Piton des Neiges; crosses, volcanic rocks of Mauritius. Analyses from Boudière<sup>5</sup>, Lacroix<sup>4</sup> and Walker and Nicolayson<sup>6</sup>. Dashed line indicates the boundary between Hawaiian tholeiitic and alkalic series<sup>7</sup>

very abundant. They are mainly dunite, occasionally grading into pyroxenite and very rarely carrying plagioclase.

The division of the lava sequences of many Hawaiian volcanoes into two main groups<sup>1</sup> can be generally matched in Réunion. The Differentiated Series of Piton des Neiges is clearly equivalent to the alkalic suite of lavas which typically forms the upper part of mature Hawaiian volcanoes, and similar rocks build the exposed part of the other Mascarene volcanoes, namely Mauritius<sup>2</sup> and Rodriguez<sup>3</sup>. The Oceanite Series of Piton des Neiges, and the lavas of Piton de la Fournaise, represent the 'primitive' basaltic suite, which in Hawaiian volcanoes is of tholeiitic type. The chemical affinities of the Réunion 'primitive' lavas are less clearly established; using the chemical data quoted by Lacroix<sup>4</sup> it can be shown that the majority of the olivine basalts contain significant amounts of normative hypersthene, which is generally a tholeiitic

characteristic, but an alkali-silica diagram (Fig. 2) indicates a composition intermediate between the tholeiitic and alkalic suites as defined by this method for the Hawaiian lavas<sup>5</sup>. The mineralogical evidence, particularly the nature of the groundmass pyroxenes, requires detailed investigation, but preliminary work indicates that Ca-poor pyroxenes are absent.

## CALEDONIAN OROGENY OF THE CENTRAL IRISH SEA REGION

By DR. W. E. TREMLETT

Department of Geology, University of Glasgow

SINCE the publication<sup>1</sup> of a suggested scheme of correlation of Caledonian structural and igneous events in Britain, further research in North Wales, both by myself and others, now allows a fuller comparison of its history with that of S.E. Ireland to give a detailed picture of the Caledonian orogeny of the Central Irish Sea region. As was pointed out previously, a consideration of this orogeny should include not only the strong initial compressions which led to widespread folding and cleavage at the end of the Silurian period but also the succeeding phases of high-angle faulting and igneous intrusion continuing long into Devonian times (ref. 1, p. 796). The initial correlation of the Caledonian events (so defined) of these two areas on either flank of the Irish Sea was based entirely on my own work<sup>2,3</sup>. The subsequent recognition by Helm, Roberts and Simpson<sup>4</sup> that the fold-phases and cleavage observed by Simpson in the Isle of Man<sup>5</sup> are also present in North Wales allows, however, a closer correlation of the earlier phases of Caledonian history.

It is clear that the  $F_2$  fold system (and its associated cleavage) described by those authors is indicative of a stress-system corresponding to that which produced low-angle thrusting in S.E. Ireland; and that these localized structural features represent the second compressional phase of the orogeny, following the more widespread folding and cleavage of the first compression ( $F_1$ ). The  $F_2$  folds and cleavage of North Wales must then represent the second cross-phase, since the earliest Caledonian intrusions of northern Lleyn (the early granodiorite suite, intruded during the much weaker third compression) post-date all the more severe deformation of the country rocks. The  $F_2$  folds and cleavage are, like those of the  $F_1$  phase, closely localized, at least in the definite examples quoted by Helm, Roberts and Simpson<sup>4</sup>. Folds and cleavage of this generation in south-eastern Lleyn have since been described by me<sup>6</sup>, but no definite examples of  $F_2$  folds or cleavage have yet been observed in the areas of the peninsula that have been examined.

Further investigations by me to cover a more extensive part of the Lleyn peninsula<sup>7</sup> have also added further information on the later Caledonian history of North Wales. It has now become apparent that a group of

E.N.E. sinistral wrenches which have displaced the early granodiorite intrusions<sup>8</sup> can be separated from the north-easterly dextral wrenches such as the Nefyn fault (ref. 3, pl. 13) despite the approximate parallelism of these two sets of fractures. The Nefyn fault is very accurately dated by the penetration of aplites of the Bodelias granodiorite up minor fractures associated with this fault, which has clearly displaced the main intrusion (ref. 3, p. 174). Moreover, the direction of compression indicated by microgranodiorite dykes of Pennant type, associated with and of the same magma type as these early granodiorites, is correct for the formation of dextral wrenches with the direction of the Nefyn fault. Hence it appears that the north-easterly dextral faults pre-date the E.N.E. sinistral displacements, which apparently formed in the later part of the third cross-phase when a new generation of magma was emplaced to form the Pistyll microgranodiorite<sup>9</sup> with a form indicative of the north-easterly compression required for the formation of E.N.E. sinistral wrench faults.

In addition to some early N.N.W. faults which formed at the same time as the intrusion of the early granodiorite suite (ref. 3, p. 173), there are also later N.W.-N.N.W. fractures in the Lleyn peninsula, which clearly chop across the E.N.E. sinistral wrenches (ref. 7, p. 11) and include faults of sinistral wrench type as well as dip-slip faults and others which contain components of both types of movement. While some of the dip-slip faults are closer to N.W. in direction and somewhat sinuous in their outcrop, other faults with an important dip-slip component share the N.N.W. direction and straightness of those fractures which are largely or entirely sinistral wrenches. Hence it appears that a series of N.N.W. sinistral faults was formed first, and later with a slight change of the stress field some of these became modified or very largely overprinted by dip-slip movements, while some new, generally shorter, dip-slip faults also formed, closer to N.W. in direction. Both phases of movement can be recognized prior to the intrusion of felsite dykes<sup>8</sup> and hence both belong to the fourth compressional phase as defined by the events of S.E. Ireland, for as has previously been pointed out<sup>1</sup> the felsites (and some of the later events) of North Wales can be closely fixed in that scale. The pre-felsite W.N.W. faults across the southern end of the

Pistyll microgranodiorite, which were included in Table 1 of ref. 1, are now known to represent an uncommon fault direction in Lleyn. The reason for their formation in that locality, while N.N.W. sinistral wrenches were forming in most other parts of the peninsula, appears to have been due to a local modification of the vertical component of the stress field by the recently emplaced Pistyll intrusion.

Table 1. CORRELATION OF THE MID-PALAEZOIC STRUCTURAL AND IGNEOUS EVENTS OF SOUTH-EAST IRELAND AND NORTH WALES, SHOWING DIRECTIONS OF MAXIMUM HORIZONTAL COMPRESSION

Structural phases	Arklow area (S.E. Ireland) —Trenlett 1959	North Wales —various sources

FOURTH CROSS-PHASE		
FOURTH COMPRESSIONAL PHASE		
THIRD CROSS-PHASE		
THIRD COMPRESSIONAL PHASE		
SECOND CROSS-PHASE		
SECOND COMPRESSIONAL PHASE		
FIRST CROSS-PHASE		
FIRST COMPRESSIONAL PHASE		

The age-relationships of some of the later intrusions of North Wales have been discussed previously (ref. 7, p. 223), and it was seen that, contrary to the sequence suggested by Greenly<sup>8</sup>, their order of emplacement is: (1) ultramafic suite; (2) felsites and granophyres; (3) dolerites. While some of the ultramafic intrusions of Anglesey appear to have a sill-like form, there is no doubt that many are essentially dyke-like (possibly with locally concordant contacts) and have an outcrop parallel to that of the country rocks only because that was the orientation of the maximum horizontal compression during their emplacement. The ultramafic rock of Pen-y-rhiwian on the mainland appears to have been intruded as a dyke up one of the E.N.E. wrench faults<sup>7</sup>. This relationship is the only item of evidence on the earliest possible age for this suite, so it is possible that the ultramafic intrusions were emplaced during the third cross-phase (prior to the extensive N.N.W. and N.W. faulting of this region), but intrusion in the early part of the fourth cross-phase appears to me more probable.

The position in the time-sequence of the felsites and granophyres of North Wales is accurately fixed not only relative to the felsites of S.E. Ireland and the preceding N.W.-N.N.W. faults of the Lleyn peninsula (see above) but also in relation to the succeeding igneous events of the fifth compressional phase<sup>8</sup>. Though some of the intru-

sions have a circular outcrop and some follow pre-existent faults<sup>8,9</sup>, many develop a N.N.E. elongation<sup>8,10</sup> indicating the direction of maximum horizontal compression (albeit a weak one) during their emplacement.

The discovery of more rocks of Garnfor type at Garn Bentryrh<sup>8</sup> suggests that the W.N.W. orientation of the intrusions of these rocks and the dolerites at Garnfor may represent a local variation of a general north-westerly stress orientation rather than an earlier part of the fifth compressional phase as was previously postulated<sup>1</sup>. The events of the fifth cross-phase have previously been described<sup>1,8</sup>, consisting essentially of the intrusion of the Yr Eifl microgranite and dip-slip movements along north-easterly faults, but, whereas these faults in the Nefyn area were once thought to have originated at this time<sup>8</sup>, it is now apparent from studies over a wider area that they already existed as part of the E.N.E. sinistral wrench system prior to the intrusions of felsites, Garnfor hybrids and Yr Eifl microgranite. The small post-intrusive movements affecting these rocks represent only reactivation of already existent faults. Some small E.N.E. sinistral displacements of the margins of felsite intrusions are perhaps more likely to have occurred during this phase than at a later stage of the fourth cross-phase.

It will be noted that the Caledonian history of North Wales is now known in more detail than at the time of my previous publication on correlations of stress-chronology<sup>7</sup>. Nevertheless, as is indicated by a comparison of this new history with the earlier version, further research of North Wales has tended to amplify rather than modify the history previously advocated. Any modifications are minor and it is clear that the history deduced earlier was essentially correct.

A new comparison of the Caledonian history of North Wales with that of S.E. Ireland on the basis of the stress chronology of the two areas is given in Table 1. It will be seen from this that the filling in of the gaps in the Caledonian history of North Wales has tended to increase the similarity of its structural sequence to that of S.E. Ireland. The new information has not required the change of position of any of the correlated events, and supports the previous tentative correlation. Moreover, the further results of research in North Wales have not required the addition of any more compressional or cross-phases, and it begins to appear as if the five cycles previously detected in the Caledonian earth-movements of the region constitute the total number (apart from the Middle Devonian movements which must also be included in this orogeny—ref. 1, p. 799). The ubiquitous severe cleavage of the first compressional phase in S.E. Ireland, and the widespread development of thrusts and associated cleavage during the second compression, indicate that these main phases of the orogeny were much more severe in the western parts of this region, while the important faulting of the third compression indicates a continuation of this state of affairs, but in the later phases there is no general rule on which area had more severe stresses applied to it. Nevertheless, though some of the compressions were stronger in one area than the other and many of the structural episodes are represented by different events on either flank of the Irish Sea, it is apparent that when the events are represented by the direction of maximum horizontal compression there is a very close similarity of the structural history of the two areas which suggests an overall control of Caledonian orogenic processes over the whole region.

## SALT WATER IN THE BOTTOM LAYERS OF TWO NORWEGIAN LAKES

By HANS HOLTAN

Norwegian Institute for Water Research, Blindern, Norway

**D**URING and after the last glacial period large areas of Norway were flooded by the sea, and the marine limit was in most places situated far above the present sea-level. Later, the sea retreated, and the lake basins in areas that had been flooded were left filled with sea-water. In deep basins in sheltered localities salt water can, because of its density, remain in the deepest layer of the lake for a long time. Consequently, trapped sea-water can still be found in the bottom layer of certain deep lakes situated below the marine limit.

In 1952 it was discovered<sup>1</sup> that lake Rørholtfjord in Telemark county, southern Norway (Fig. 1), situated 60 m above sea-level, has a layer of salt water extending from a depth of 134 m to the bottom (147 m).

(Fig. 1), were found to be meromictic, with salt water in the bottom layer.

The bedrock of the catchment area of these lakes (Fig. 2) is built up of gneisses and granite gneisses. The topography is irregular and most of the area is covered by only a thin layer of moraine material. Between Birkelandsvatn and Tronstadvatn there is a small moraine, and there are remains of moraine material in some places along their shores. In the catchment area there is a good deal of marshland and the soil is peaty. Most of the area is covered by coniferous forest, particularly pine (*Picea abies* and *Pinus silvestris*). With regard to the geological origin of the lakes, they are eroded along a fault-line, and their shores are very steep. Consequently the lakes are protected from the wind by the surrounding hills and the locality has a rather sheltered character.

Tronstadvatn is situated about 13 km from the sea and Birkelandsvatn about 22 km. The lakes were sounded using a 'Simrad' echo sounder (Simonsen Radio A/S, Ensjeveien 18, Oslo). The morphological details for the lakes are given in Table 1.

Tronstadvatn and Birkelandsvatn have catchment areas of about 53 km<sup>2</sup> and 22 km<sup>2</sup> respectively. According to data from the Norwegian Watercourse and Electricity Board<sup>2</sup> the mean drainage in this area is about 40 l./sec./km<sup>2</sup>, which gives 183,000 m<sup>3</sup> and 78,000 m<sup>3</sup> of drainage water per 24 h for Tronstadvatn and Birkelandsvatn respectively. The 'theoretical renewal time' of the whole

Fig. 1. Norwegian lakes with trapped sea-water

Since then, Strøm has also described<sup>3</sup> two similar lakes in northern Norway (Fig. 1). Botnvatn, situated 12 m above sea-level in the Salten district, is saline from a depth of 102 m to the bottom (113 m). Similarly, Rørholtfjord, 3 m above sea-level in the Lofoten district, has salt water from 44 m to the bottom (92 m). Strøm maintains that there is no doubt that the salt water in the bottom of these lakes is the remains of previous sea-water.

In 1963, during a limnological investigation of several lakes in the Kristiansand area in the south-western part of Norway, two lakes, Tronstadvatn and Birkelandsvatn

Fig. 2. Tronstadvatn and Birkelandsvatn, the catchment area.

Table 1. TRONSTADVATN AND BIRKELANDSVATN  
Morphological details

	Tronstadvatn	Birkelandsvatn
Altitude above sea-level	41	43
Maximum depth, m	98	69
Average depth, m	37	23
Surface area, km <sup>2</sup>	2.0	0.8
Volume, million m <sup>3</sup>	76.5	16.7
Maximum length, km	4.9	3.0
Maximum breadth, km	0.8	0.9
Cryptodepression, m	57	26

Table 2. FIGURES FOR COLOUR (mg Pt/L) AND COD (ml N/100 KMnO<sub>4</sub>/L) IN SOME LAKES IN THE KRISTIANSTAD AREA

Locality	Colour, mg Pt/L	ml N/100 KMnO <sub>4</sub> /L
Rossevatn	13	25.0
Tronstadvatn	15	27.5
Hammervatn	18	31.3
Reivvatn	21	33.8
Birkelandsvatn	23	36.5
Bjelklandsvatn	25	42.5
Sukkevatn	29	46.3
Storvatn	45	56.3

water mass is thus about 14 months for Tronstadvatn and 7 months for Birkelandsvatn.

Down to about 78 m in Tronstadvatn and 33 m in Birkelandsvatn the lakes are dimictic, and every spring and autumn the water turns over; during winter and summer a thermal stratification is established. During the summer stratification period the thermocline is situated at a depth of 7-8 m in both lakes. From 78 m in Tronstadvatn and 33 m in Birkelandsvatn the temperature increases with increasing depth (Fig. 3) and here the temperature conditions are constant during the year.

The pH and 'hardness' of the fresh water in Tronstadvatn and Birkelandsvatn are low, as in most of the other lakes in south Norwegian bedrocks. The lakes receive a load of allochthonous organic material from the catchment area, but, compared with other lakes in the area, the amount of humus present in the water is relatively small (Table 2). This is because the biological decomposition of such material is very effective in these comparatively large and deep lakes.

In the aerated water masses the oxygen saturation value lies between 80 and 90 per cent, but in the chemocline layer the value decreases from about 80 per cent to 0.

Fig. 3. Some chemical components in Tronstadvatn and Birkelandsvatn

The water has low concentrations of iron and manganese ions. These ions are probably associated with humic material carried to the lakes with the incoming drainage water. As is usual in surface waters in this region, the fresh water of the two lakes has a low content of chloride and sulphate. The concentration of these ions increases with depth in the fresh-water layer and the same applies to sodium and potassium.

Tronstadvatn and Birkelandsvatn are both meromictic lakes, and they have high concentrations of salts, methane and carbon dioxide in the deep water. The stagnant water in Tronstadvatn is situated between 78 m and the bottom (98 m), and has a volume of  $2.5 \times 10^6$  m<sup>3</sup>. In Birkelandsvatn the stagnant water extends from 33 m to the bottom (69 m) and the volume is  $2 \times 10^6$  m<sup>3</sup>.

The qualitative and quantitative composition of the salt water is somewhat different for the two lakes, as can be seen from Table 3.

Table 3. CHEMICAL COMPOSITION OF THE STAGNANT WATER IN TRONSTADVATN AND BIRKELANDSVATN AND OF SEA-WATER SALINITY (35 parts per thousand)

Parameter	Tronstadvatn	Birkelandsvatn	Sea-water (35‰)	B/T
$\kappa_s \times 10^6$	2,500	8,800	c. 48,000	3.5
Cl, mg/L	670	3,350	19,800	5.0
Br, mg/L	4	*	66	0.06
I, mg/L	165	600	11,100	3.7
Na, mg/L	5.2	10.3	290	2.0
K, mg/L	140	840	420	6.0
Ca, mg/L	102	300	1,330	3.0
Mg, mg/L	150	115	0.001-0.05	0.75
Fe, mg/L	10	1.2	0.001-0.01	0.12
Mn, mg/L				

\* Not analysed.

The figures in the last column (B/T) indicate the ratio between the concentrations of the different components in Birkelandsvatn and Tronstadvatn.

Table 4. RATIOS BETWEEN THE CONCENTRATION OF SOME COMPONENTS IN TRONSTADVATN, BIRKELANDSVATN AND SEA-WATER (35 parts per thousand)

Locality	Cl/Br	Na/K	Cl/Na	Br/Na
Tronstadvatn	165	23	4	1/41
Birkelandsvatn	60	60	5.6	
Sea-water	300	30	1.8	1/168

Table 3 shows that most of the components are present in greater concentrations in Birkelandsvatn than in Tronstadvatn except for iron and manganese, the concentrations of which are greater in Tronstadvatn. The concentration ratios between various components are shown in Table 4.

Table 4 shows that the ratio between chloride and bromide is only half as high in Tronstadvatn as in sea-water. The relationship between sodium and potassium is almost the same in Tronstadvatn as in sea-water, but only half that in Birkelandsvatn. There is no apparent correlation between chloride and sodium or bromide and sodium. It is not, therefore, possible on this basis to say whether the stagnant water in Tronstadvatn and Birkelandsvatn is the remains of previous sea-water.

Comparing the ratios of chloride and sodium concentrations in the fresh water and the stagnant water we find that these ratios increase with depth, as Table 5 shows.

In the fresh water in Tronstadvatn the chloride/sodium ratio is the same as in sea-water, but this is not so for the stagnant water. In both the fresh and the stagnant water the chloride/sodium ratio is greatest in Birkelandsvatn.

Table 5. RELATIONSHIP BETWEEN CHLORIDE AND SODIUM IN TRONSTADVATN AND BIRKELANDSVATN

	Depth (m)										
Locality	1	20	32	33	34	50	70	77	78	79	80
Tronstadvatn	1.7					1.8	1.8	2.1	4.2	4.1	4.1
Birkelandsvatn	2.2	2.8	3.2	4.6	5.5	5.6					

The origin of the salt water in Tronstadvatn and Birkelandsvatn is of considerable interest, especially as it can throw some light on the location of the marine limit in south-west Norway. Danielsen<sup>4</sup> maintained that the marine limit in the Kristiansand area is situated about 40–50 m above the present sea-level. On the other hand, Andersen<sup>5</sup>, in a comprehensive investigation of the quaternary geology of south-west Norway, states that the marine limit in the Kristiansand area is situated between 16 and 28 m above the present sea-level.

The geology of the area in which these lakes are situated is such as to preclude the idea that the salt water gained its mineral contents from the bedrock. It seems very likely, therefore, that the salt water in the bottom of the two lakes is of marine origin. This constitutes powerful evidence that the marine limit in this region was situated at least 40 m above the present sea-level.

The fact that the concentration ratios of the ions in the salt water of the lakes are different from those of sea-water does not necessarily argue against the sea-water theory. It is quite likely that the slow addition of organic and inorganic allochthonous material from the catchment area over thousands of years could have altered the composition of the salt water in the period that has elapsed since the lakes became isolated from the sea. Furthermore, dilution and selective adsorption of the various salts could have occurred in such a way that their ratios to each other are now quite different from what they are in sea-water.

It is, then, reasonable to suppose that the salt water in the bottom of Tronstadvatn and Birkelandsvatn has originated from sea-water left behind after the last glacial period. This is considered to be evidence for placing the quaternary marine limit in this area at a level at least 40 m above the present sea-level.

## ACCELERATED DEFORMATION OF ROCK SALT AT ELEVATED TEMPERATURE

By T. F. LOMENICK and R. L. BRADSHAW

Health Physics Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee

CHEMICAL reprocessing of power reactor fuel produces a chemically complex and hazardous effluent which cannot be handled by conventional waste-disposal methods. Special methods of disposal are required to contain these wastes for centuries, thus preventing the escape of fission products to the environment. The most promising method for disposal of high-level, heat-generating, power reactor wastes is the conversion of liquid wastes to solids, followed by the ultimate disposal of the solids in a salt mine<sup>1–3</sup>.

In order to be able to design a radioactive waste disposal facility in a salt mine, it is necessary to be able to predict the effects on mine stability of both supporting-pillar stresses (produced by the superincumbent Earth strata), and elevated temperatures (produced by radioactive decay of the fission products in the waste).

Recent work by Serata<sup>4</sup> and Obert<sup>5</sup> at ambient temperatures has shown that flow in rock-salt mines may be approximated by testing scale-model specimens uniaxially. It is generally known that elevation of the temperature increases the creep rates of stressed rock-salt specimens, but no data or experience are available which can be directly applied to mine conditions.

To simulate pillar, roof and floor conditions which would exist in mined cavities in rock salt, sample specimens are fabricated to represent scale models of salt pillars and their surrounding rooms. The test specimens used in the work recorded here are cylindrical in shape, with a portion of the centre ground out to form the pillar and surrounding rooms (Fig. 1). By 'epoxying' steel rings around the ends of the samples, effective confining pressure is applied to the roof and floor portions of the models when they are loaded. Constant uniaxial loads are applied to the models by hydraulic compression testers having capacities up to 300,000 lb. (1 lb. = 0.453 kg). Cavity closure is measured by mounting two dial gauges 180° apart on the rings. All tests were conducted in a controlled-temperature room equipped with automatic dehumidifiers to prevent condensation on the samples during extremely damp periods. Elevated temperature tests were performed with the specimens inside a cylindrical heating jacket and with barrier heaters on top and bottom between the specimen and the platens.

All model pillars were fabricated from 6-in.-diam. (1 in. = 2.54 cm) cores of rock salt taken in the mine of the Carey Salt Co., Lyons, Kansas. The pillars measure 4 in. in diameter and 1 in. in height. Tests were conducted at temperatures of 22.5° C, 60° C and 100° C for axial loads of 2,000, 4,000, 6,000, 8,000 and 10,000 lb./in.<sup>2</sup> (1 lb./in.<sup>2</sup> = 0.0703 kg/cm<sup>2</sup>). Durations of the tests varied from a few hours to several thousand hours. For certain temperature and load combinations, duplicate or triplicate tests were run in order to obtain an approximate measure of variation from sample to sample. Eventually, this will be done for most of the combinations. By the middle of February 1965, about 25 pillar models had been tested in this Laboratory.

From these tests it was observed that the deformation of the pillars increased markedly with increasing loads. However, even more significant was the greatly accelerated creep rates of the salt at elevated temperatures. The

Fig. 1. Model of salt pillar

Fig. 2. Deformation of model rock salt pillars

cavity closures with time for models axially loaded to 4,000 lb./in.<sup>2</sup> and 6,000 lb./in.<sup>2</sup> at temperatures of 22.5° C, 60° C and 100° C are shown in Fig. 2. These curves, along with those at higher and lower stresses, all show general similarities. For each curve, there is initially a high creep rate that decreases with time. Tests of longer duration show that creep rates continue to decline even after 5,000 h. This is in agreement with measurements that we have made in salt mines which show that closure rates are still decreasing with time in openings up to 12 years. At room temperature (22.5° C) the percentage cavity closure (inches shortening of the pillar) for the 4,000-lb./in.<sup>2</sup> sample was about 3 per cent after 300 h and for the 6,000-lb./in.<sup>2</sup> model approximately 10 per cent, while for the 4,000- and 6,000-lb./in.<sup>2</sup> samples heated to 60° C the closure for the same period of time was about 10 and 25 per cent, respectively. When the temperature is increased to 100° C, the increase in the rates of cavity closure is even more pronounced. It is also of interest that the deformational behaviour of the salt pillar loaded to 4,000 lb./in.<sup>2</sup> at a temperature of 60° C is approximately the same as the behaviour of the sample loaded

to 6,000 lb./in.<sup>2</sup> at room temperature. Also, the creep curve for the 4,000-lb./in.<sup>2</sup> model at 100° C shows a close correlation with the behaviour of the 6,000-lb./in.<sup>2</sup> sample at 60° C. This strongly suggests that salt pillars subjected to elevated temperatures will behave like pillars under higher stresses.

We were encouraged to extend the pillar-model tests to elevated temperatures after we had analysed the results of a series of seven tests at ambient temperature which were performed for us by the Applied Physics Laboratory of the Bureau of Mines<sup>1</sup>. To these data we fitted an empirical equation, extrapolation of which produced predicted creep rates which were in reasonable agreement with vertical and horizontal creep-closure rates which we have been measuring in the Kansas mines since 1959 (ref. 6). The following empirical equations have been fitted to the results of the Oak Ridge National Laboratory pillar-model tests for times from 10 h on. The equation would require modification to fit the data from zero time.

$$\dot{\epsilon} = 3.2 \times 10^{-36} T^{15.5} \sigma^{2.5} t^{-0.55}$$

$$\epsilon = 9.2 \times 10^{-36} T^{15.5} \sigma^{2.5} t^{0.55} + A$$

where  $\dot{\epsilon}$  = strain rate (vertical convergence,  $\mu$  in. in.<sup>-1</sup> h.<sup>-1</sup>);  $\epsilon$  = cumulative deformation ( $\mu$  in. in.<sup>-1</sup>);  $T$  = absolute temperature (°K);  $\sigma$  = average pillar stress (lb./in.<sup>2</sup>);  $t$  = time (h); and  $A$  = total deformation at 10 h.

At ambient temperature these equations give approximately the same results as those derived from the Applied Physics Laboratory tests. Although the data are still too sparse to attempt a statistical analysis, the results appear to corroborate a previously developed hypothesis<sup>7</sup> that the effect of elevating the temperature is essentially the same as that of increasing the average pillar stress, and that the relationship between creep rate and axial stress follows the same power law regardless of the temperature.

## LOGIC OF COMPUTER-BASED INTRINSIC CLASSIFICATIONS

By PROF. W. T. WILLIAMS\* and DR. G. N. LANCE  
C.S.I.R.O. Computing Research Section, Canberra, Australia

WE believe that the rationale of the numerical techniques for the classification of elements into sets has been widely misunderstood. This misunderstanding has given rise, on the one hand, to exaggerated respect for the 'absolute' nature of the classifications so produced and, on the other, to unmerited summary dismissals of many such systems (see, for example, the strictures of Seal<sup>1</sup> on the work of Sokal and Sneath<sup>2</sup>). The intention of this article is to place these methods in their logical context, to reveal those areas in which empirical tests are appropriate, and to announce computer programmes capable of carrying out such tests on a more extensive scale than his hitherto been possible.

\* Permanent address: Department of Botany, University of Southampton.

### The Statistical Problem

From a statistical point of view any classificatory system involves three terms: the individuals that are to be classified, the attributes by which these individuals are described, and the uses to which the classification is to be put. Any one of these three may in principle be either a finite or an infinite set; if a set contains more elements than can conveniently be individually considered, we shall regard it as infinite. The uses will therefore only be treated as a finite set if they are all known, and in this case an extrinsic classification (that is, a classification with respect to one or more external criteria, such as that suggested by Macnaughton-Smith<sup>3</sup>) is required; we are not here

concerned with this case. The attribute-set, though always in principle infinite, is in practice always finite since no use can be made of information we do not possess. In intrinsic classifications, therefore, there are only two basic situations according to whether the individual-set is finite or infinite. Of the eight possible situations (finite or infinite sets of individuals, attributes or uses), only the case with all three terms finite is strictly non-probabilistic, because completely determinate, and this case is unlikely to arise in practice. However, if the user constates the only infinite set, it will be difficult to interpret the assigning of a probability or a significance-level to any fusion or separation of individuals or groups; it will normally only be possible to assess a result as 'informative' or 'profitable'. It is in this wider sense that Williams and Dale<sup>4</sup> have used the term 'non-probabilistic'.

The distinction between the two basic situations (probabilistic, or non-probabilistic in the wider sense) may to the user appear artificial or unimportant; but they represent two quite distinct statistical problems which we shall deal with in turn.

(1) *The case of the finite population.* The classic example of this case is that in which the elements are taxa the characteristics of which have been extracted from the relevant literature. A more troublesome case is that in which the characteristics have been obtained from an examination of representative specimens (for example, type-specimens in the nomenclatural sense). Here it is essential for the user to decide whether these are to be regarded as specimens (that is, individual samples from a population and thus subject to error) or as types (that is, convenient summaries of information which define taxa, as distinct from merely illustrating them).

The practical test in border-line cases is primarily whether the user does or does not wish to question the distinctness of the elements. If he does not, then these elements are members of a finite population: they are as completely defined as the user wishes, they are postulated as different, and the null hypothesis that they are samples from a larger population is highly artificial. This situation is non-probabilistic in the wider sense defined here, and it remains to explore the status of the information then produced by 'cluster-seeking' or 'similarity' methods. Consider, as an analogy, a family of ten children; to their mother they are unique and precisely known entities. She may nevertheless find it useful to group them in order to convey information economically: into, for example, two musical and eight unmusical, or into six boys and four girls. The musical classification would only be useful in a very specific context; but the sex classification would involve differences on many other attributes, and would serve a variety of purposes. Such a classification is, in fact, predictive; the precise purpose for which it is to be used may not be known at the time that it is made, and its function is simply to provide groupings which it is hoped will involve attributes additional to those immediately under consideration.

Two important conclusions follow: (a) Classifications so produced can never be true or false, or even probable or improbable; they can only be profitable or unprofitable. To define an optimum method we should have to formalize the situation sufficiently to estimate, and thence to maximize, the expected profitability. The purpose of such methods is not to displace the intuitive taxonomist, but to suggest to him potentially fruitful lines of investigation. (b) Such classifications are not unique. The ten children might equally well have been divided into three infants, five at school, and two out at work; and this grouping would have been more profitable than the sex-grouping for some purposes, less so for others. The classification must be tested empirically by the observation of further appropriate attributes.

If, however, the user does not choose to regard his taxa as inviolate, an alternative strategy is available; he may postulate that the differences between two similar taxa

might have arisen as a result of sampling errors, and he may then elect to analyse his finite group as if it were a sample from a hypothetical infinite population. This is in effect the strategy suggested by Goodall<sup>5</sup>. So far as the inter-relationships between elements are concerned, the group under investigation is regarded as a model of an infinite population; each pair of taxa can then be associated with a probability that the resemblance of the two elements has arisen by chance. This system has the interesting property that the degree of similarity between two individuals is related to the homogeneity of the group as a whole. (This concept is familiar to taxonomists who are well aware that the orders of differences which separate tribes in a homogeneous family such as the Labiatae would barely suffice to distinguish genera in the more diverse Ranunculaceae.) Goodall (personal communication) has under development a corresponding probabilistic cluster-analysis system; but even when this is available the computation involved is likely to preclude the use of the method in any but critical cases. For the 'primary survey' of taxonomy—the delimitation of groups likely to be worthy of further study—the user may normally be expected to use empirical coefficients in the predictive sense outlined here.

(2) *The case of the sample.* In ecology (in classification of vegetation) the population under investigation is usually a set of quadrats; in microbiology it may be a set of isolates. In such cases the population is manifestly a sample from a larger population, and is subject to bias and error in the sampling. Three strategies are now available:

(a) The user may, providing he does so overtly, choose to process the data as if it were a finite population. It then follows that, whereas with a truly finite population the results can be at worst unprofitable, they can now in addition be misleading. This strategy therefore imposes on the user a more stringent test of profitability; in ecology a habitat survey will provide such a test, as will the investigation of the behaviour of further attributes in taxonomy.

(b) The original classification may be applied to a fresh sample by means of an allocation rule, and the resulting sub-division appropriately tested for significantly high information-content; this strategy has received less attention than it deserves. Alternatively, but less satisfactorily, a second sample may be classified independently and the results compared; no precise test of the validity of such a comparison has been suggested, but groupings recognizable as common to the two analyses are unlikely to be due to sampling errors, though they may be due to bias.

(c) The user may choose to work in a genuinely probabilistic situation such as is provided by the Goodall coefficient. He has more commonly wished to take advantage of the kind of 'similarity' defined by the empirical systems, and to assign probabilities to the relationships so obtained. The difficulties of this approach have been briefly discussed by Williams and Dale<sup>4</sup>; the problem is notoriously intractable and, although it has given rise to a formidable literature, only in the case of the rarely used information statistic can there be said to be a satisfactory solution. Taxonomic writing has sometimes seemed to us to imply that this particular type of strategy is the normal one, and that its state of development is substantially satisfactory; such a view cannot but arouse misgivings.

### New Computer Programmes

We are not here concerned with monothetic classifications, which use a divisive strategy, but with the polythetic agglomerative ('similarity') methods which have been widely used for taxonomic purposes. In those cases in which empirical classifications can be justified, it is, as we have already implied here, to be expected that

different types of problem will be best served by different systems; the distinction frequently made in the literature between 'size coefficients' and 'shape coefficients' is a familiar example. Nevertheless, few comparative studies have been made of different systems on the same set of data. This is largely because any one worker has usually had access to a very limited range of alternatives; and we have therefore written, for the Control Data 3600, a flexible programme to facilitate such investigations. The specification, in outline, is as follows:

**Data (i) type:** qualitative or quantitative. Since the programme is intended for methodological study, provision has not been made for missing or inapplicable attributes. Automatic transposition is available for 'inverse' classifications of attributes\*.

**Data (ii) dimensions:** fast versions of the present programmes will accommodate 100 individuals specified by 50 attributes. Alternative versions, using magnetic tape as an intermediate store, will accommodate populations of very considerably increased size.

**Sorting strategies.** Both nearest-neighbour and group sorting are provided. The group sorting is of the type in which a group is replaced on formation by the co-ordinates of its centroid (or, in the case of the information statistic, by a definition of the whole group).

**Coefficients.** Four basic coefficients are provided:

(i) **Squared Euclidean distance.** Provision is also made for initial standardization of attributes to zero mean and unit variance, or for the reading in of a vector of weighting coefficients.

(ii) **'Non-metric coefficient'.** In the conventional notation of a  $2 \times 2$  table, this is  $(b + c)/(2a + b + c)$ : the quantitative counterpart between two vectors ( $x_1$ ) and ( $x_2$ ) is  $(\sum |x_{1j} - x_{2j}|)/\sum (x_{1j} + x_{2j})$ . It is open to mathematical objections, but has so commonly been used in ecology that it is important for comparative purposes.

(iii) **Correlation coefficient.**

(iv) **Information statistic.** If a group of  $n$  elements is defined by  $p$  attributes, and if the  $j$ th attribute is possessed by  $a_j$  elements, the loss of information on formation of the group from its elements may be defined by:

$$I = pn \log n - \sum_{j=1}^p [a_j \log a_j + (n - a_j) \log (n - a_j)]$$

The coefficient used for discrimination is the increase in  $I$  on fusion, which is to be minimum. It is available in this form only for qualitative data, and cannot meaning-

fully be used with nearest-neighbour sorting since it is then a constant multiple of Euclidean distance.

To allow as much space as possible for data, three separate programmes are provided: **QUALNEAB** (qualitative data, nearest-neighbour sort), **CENTROID** (qualitative or quantitative data, centroid sort) and **NUMNEAB** (quantitative data, nearest-neighbour sort).

Dr. J. M. Lambert has made a preliminary examination of a set of comparative runs of all methods on two qualitatively specified ecological populations. The results already suggest that, as is to be expected on mathematical grounds, centroid sorting is always more powerful than nearest-neighbour sorting; they also give grounds for the tentative suggestion that the information statistic is the most informative of the coefficients. A full account of these analyses will in due course be submitted for publication in an ecological journal. Meanwhile, users with other types of data may wish to undertake similar comparative studies, and specifications of the programmes can be obtained from Dr. G. N. Lance.

### Problem of Mixed Data

A striking characteristic of much genuine taxonomic data is the high proportion of multi-state attributes. These cannot in all cases be realistically dichotomized; nor can the separate states be regarded as qualitative attributes, since the states are not normally independent and spurious negative associations immediately arise. Taxonomists cannot be expected to use numerical methods until these are capable of processing their data without distortions imposed solely for the convenience of the method. The Goodall coefficient will accommodate mixed data, but a simpler method is desirable for everyday use. We have therefore developed a cruder empirical system based on the 'non-metric coefficient', which will accommodate qualitative, quantitative and multi-state attributes; it has been assembled into a programme (**MULTIST**) which uses centroid sorting. We regard this programme as still experimental, but it has given promising results on small-scale problems and is available for more extensive tests.

## NUCLEOLAR AND CYTOPLASMIC RIBONUCLEIC ACID INHIBITION BY EXCESS THYMIDINE

By DR. FREDERICK H. KASTEN, FREDY F. STRASSER and MARIAN TURNER

Pasadena Foundation for Medical Research, Pasadena, and Department of Anatomy, University of Southern California School of Medicine, Los Angeles

AT low concentrations, actinomycin D inhibits DNA-dependent RNA synthesis without affecting DNA replication<sup>1</sup>. At the cytological level, this action manifests itself in the nucleolus, resulting in an inhibition of nucleolar RNA synthesis with failure to form ribosomal RNA (ref. 2) and a peculiar sorting out of the fine-structural components of the nucleolus<sup>3-5</sup>. During the course of an investigation of nucleoprotein synthetic patterns in synchronized mammalian cells, we obtained evidence for a similar selective inhibition of nucleolar RNA synthesis resulting from treatment with relatively high concentrations of thymidine.

Excess thymidine was first reported to induce partial synchrony by Xerxes<sup>6</sup>. An improved double-blocking technique has since been shown to induce synchrony in cultures of heteroploid human kidney cells<sup>7</sup>, HeLa cells<sup>8</sup> and diploid Chinese hamster ovary cells<sup>9</sup>. By adjusting the two excess thymidine exposures to coincide properly with the time parameters of the mitotic cycle, such cells then enter the S phase in a synchronized burst following transfer to normal medium. This conclusion is supported by our observations on CMP cells using Coulter electronic cell counts, mitotic counts, phase-contrast time-lapse cinematography film records, and tritiated thymidine

autoradiography<sup>10</sup>. Observations on thymidine inhibition of nucleolar RNA synthesis and cytoplasmic RNA are described in detail in this article.

A newly developed epithelial line of human adenocarcinoma cells was used. This rapidly growing line is designated as the CMP line (the growth characteristics, cytogenetics, and ultrastructure of CMP cells will be described in another publication from this laboratory) and is now in its 55th passage. All procedures to be described were carried out in a 37° C warm room in order to minimize temperature fluctuations and improve cell synchronization. Cells were grown in Eagle's medium plus 10 per cent foetal bovine serum, plus penicillin (100 units) and streptomycin at 50γ/ml. Trypsinized cultures were seeded on to coverslips in Yerganian tubes at a density of 20,000 cells per ml. and grown for 3 days. While in the logarithmic growth phase cultures were blocked for 24 h with 2.5 mM of thymidine. The blockage was broken by washing cells 3 times in pre-warmed Gey's balanced salt solution and incubating in normal medium for 15 h. A second thymidine blockage was imposed for 24 h.

At the end of the second thymidine treatment, tritiated uridine was added for 1 h to the thymidine-rich medium to give 20 μc./ml. (Schwarz lot 6501, 4.42 c./mM). Randomly growing cells were likewise exposed to labelled uridine for 1 h. Cells were fixed in Carnoy's acetic alcohol (1:3), brought to water, treated with 5 per cent cold trichloroacetic acid for 15 min to remove labelled RNA precursors, washed in water, dried, and covered with AR 10 stripping film. Duplicate sets of slides were stored at 4° C for 4–8 days. Preparations were developed in Kodak D19 and stained with haematoxylin and eosin. A third set of slides from the same experiment, but unlabelled, was fixed in 95 per cent methanol and stained by May–Grünwald–Giemsa for mitotic counts.

The mitotic rate in untreated randomly growing cells was 3 per cent. This population of interphase cells exhibited a uniformly heavy nucleolar and a moderate nuclear labelling in approximately 90–95 per cent of all cells; cytoplasm was lightly labelled (Fig. 1). The density of label in nucleolus, nucleus and cytoplasm was approximately in the proportions of 6:3:1 respectively. It was not possible to make exact grain counts because of the intense labelling, but the intracellular pattern of incorporation was evident. There was no labelling in mitotic cells. Thymidine-blocked cells had a mitotic rate of 0.3 per cent—10 times less than controls, demonstrating an almost complete premitotic block. Arrested cells appeared cytologically normal except for averaging larger nuclei than controls. Nuclear RNA labelling density was somewhat less than controls, but there was a complete absence of uridine incorporation into the nucleoli and cytoplasm (Figs. 2, 3). Phase-contrast observations were made under high magnification to verify that unlabelled areas resembling nucleoli in size and distribution were, in fact, these structures (Figs. 4, 5). More than 96 per cent of the labelled nuclei contained unlabelled nucleoli and cytoplasm. In the remaining 4 per cent, all nucleoli in each cell were equally labelled and to the same density as in controls. Blockage of RNA synthesis was reversible, as demonstrated by the fact that when excess thymidine medium was replaced by normal medium, there began a rapid incorporation of uridine into nucleoli during the first hour, amounting to about 75 per cent of controls. The amount of labelled RNA in the nucleoli and cytoplasm reached normal levels within 1–2 h.

Bootama *et al.*<sup>7</sup> state that cells blocked with excess thymidine are in the *S* phase of the cell cycle. Their results appear inadequate to support this conclusion since their evidence is based on the fact that cells were actually labelled with tritiated thymidine after being returned to normal medium—in effect, after the block was removed. They also observed a peak mitotic burst 6 h earlier than expected if the blockage was actually in early *S* phase.

In a recent abstract, Puck<sup>8</sup> also stated that thymidine-blocked *S3* HeLa cells are accumulated at the beginning of *S*. In support of the views of the foregoing authors is the finding that excess thymidine inhibits DNA synthesis<sup>11</sup>. In our experiments, cells are blocked with 2.5 mM of thymidine. When tritiated thymidine is added to such blocked cells in labelling doses, it is diluted 1,000 times by unlabelled thymidine. Under these conditions it would be surprising to see any evidence of DNA synthesis. In fact, we do not observe any labelled nuclei in blocked cells after exposure to 'diluted' tritiated thymidine for 1 h (New England Nuclear Corp. lot 108-55-1A-114, 8.7 c./mM, 12.5 μc./ml.). It should be possible to circumvent this difficulty and decide unequivocally whether DNA synthesis occurs in double-blocked cells by employing other DNA precursors besides thymidine. Feulgen cytophotometry may also help in clearing up this point. Judging from the timing of the peak mitotic burst observed in our experiments, the blockage appears to be in the *G1* or very early *S* phase. A more definitive conclusion as to the nature of the block must await further investigation as already indicated here. For the present we can assume, for theoretical considerations, that there is a complete cessation of DNA synthesis.

The accumulation of cells in the *G1* or early *S* phase by excess thymidine is the most obvious effect displayed. A second, and what appears to us to be a more significant action, is the selective inhibition of uridine incorporation into nucleolar RNA and a lack of cytoplasmic labelling. Chromosomal RNA synthesis is depressed slightly. These results, in regard to nucleolar and cytoplasmic RNA inhibition, are similar to those obtained with actinomycin *D* (ref. 2). The mimicry of results should not be construed to mean that the molecular mechanism of action is necessarily the same in both cases. On one hand, actinomycin *D* combines with the DNA template<sup>1</sup> and prevents the action of DNA-dependent RNA polymerase<sup>12,13</sup>, while excess thymidine is thought to inhibit DNA synthesis by blocking the formation of deoxycytidine triphosphate from cytidine-5'-phosphate<sup>8</sup>. The fact that nucleolar RNA synthesis is selectively blocked demonstrates, in accord with previous observations<sup>2,14-16</sup>, that chromatin RNA synthesis is largely independent of nucleolar RNA synthesis and that there exist at least two different extracytoplasmic fractions. Since tritiated uridine was available for 1 h in control cells of our experiments, there was sufficient time for nucleolar RNA to become labelled and to provide ribosomal components of cytoplasmic RNA (ref. 17). The fact that both nucleolar and cytoplasmic labelled RNA are eliminated by excess thymidine is probably due to the failure of nucleolar RNA to be formed which, in turn, allows no ribosomal RNA to be produced. These experiments do not exclude the possibility that excess thymidine acts as a competitive inhibitor for uridine or that cytoplasmic RNA synthesis is blocked independently of nucleolar RNA.

According to Smellie<sup>18</sup>, two different enzyme systems are found in nuclei that catalyse the incorporation of all 4 ribonucleotides into RNA. Both systems require a DNA primer and one also requires an RNA primer. Furthermore, RNA polymerase, a nucleolar constituent in animal cells<sup>19</sup>, appears to be naturally associated with DNA (ref. 20) and is required for RNA synthesis. Since the actinomycin *D*-DNA complex inhibits both RNA polymerase and DNA polymerase<sup>20</sup>, there is a quantitatively selective effect on RNA synthesis. It is suggested that nucleolar DNA synthesis triggers nucleolar RNA synthesis and also chromatin DNA synthesis. There is recent evidence that early replicating DNA of the nucleus plays a vital part in cell survival<sup>21</sup>. If it should be demonstrated that early replicating DNA is associated with the nucleolus, the argument will be further strengthened. Our observation of complete nucleolar and cytoplasmic RNA inhibition in thymidine-blocked cells (when DNA synthesis is inhibited) is consistent with the hypothesis

Figs 1-5. CMP cells exposed to tritiated uridine at  $20 \mu\text{g/ml}$  for 1 h and fixed in acetic alcohol (1-3). Developed *AR 10* autoradiographs, stained lightly with haematoxylin and eosin and photographed by bright-field except for Fig. 4. (Figs. 1, 2, 4-5,  $\times 1700$ ; Fig. 3  $\times 660$ ).

Fig. 1. Control cells demonstrate intense tritiated-uridine incorporation into nucleoli (see arrows for some examples); somewhat less uptake into chromatin RNA, and light cytoplasmic RNA labelling.

Figs. 2 and 3. Double thymidine-blocked cells. Note lack of nucleolar and cytoplasmic RNA labelling. Slight background labelling.

Fig. 4. Phase-contrast photomicrograph of a labelled cell which had been blocked with thymidine. Focal level is just below film. Arrow directs attention to nucleolus (nu).

Fig. 5. Same cell as in Fig. 4 but in bright-field. Focal level is on silver grains. Arrow points to unlabelled nucleolus (nu).

that nucleolar RNA synthesis is dependent on DNA synthesis and specifically the DNA localized within the nucleolus.

## CHEMICALLY INDUCED DELAYED GERMINAL MUTATION IN *Drosophila*

By DR. THOMAS ALDERSON

Department of Genetics, University of Cambridge

IT has long been recognized that there is a marked similarity of genetic effects in the production of gene mutation and chromosome breakage by X-irradiation and chemical mutagens. However, one notable difference between them was soon shown to be the high frequency of visible-mosaics (mainly for bristle mutations) produced after chemical treatment of *Drosophila*<sup>1</sup>.

As discussed here, the phenomenon of mosaicism is to be understood as the co-existence of somatic and/or germinal cells of different genetical constitution (for a mutation) in one and the same individual organism. The organism is said to be somatically-mosaic when mutation affects a proportion of the somatic cells, and germinally- (or gonadically-) mosaic when a proportion of the germ cells is affected.

This article reports the induction of germinal-mosaicism for sex-linked recessive lethal mutations after treatment of spermatozoa of *Drosophila melanogaster* by adult feeding of two monofunctional ethylating agents (diethyl sulphate and ethyl methanesulphonate), and *N*-nitrosomethylurea; mosaicism is afterwards detected by investigating the distribution of sex-linked recessive lethal mutations in the germinal tissue of the embryos produced from fertilization of untreated ova by the treated spermatozoa. In particular, ethyl methanesulphonate and *N*-nitrosomethylurea are found to produce the highest rates of mutation yet recorded in *Drosophila*, giving frequencies of sex-linked recessive lethal mutations of about 70 per cent. Formaldehyde, which was also tested, was found not to produce a significant increase in germinal sex-linked recessive lethal-mosaicism when administered by a larval feeding method.

The ethylating agents were selected for study, since previous tests for the induction of visible sex-linked mutations after treatment of *Drosophila* spermatozoa with diethyl sulphate indicated that mutations were originating mosaically<sup>2</sup>. *N*-nitrosomethylurea was selected for investigation, because tests showed that it was an extremely potent mutagen. Formaldehyde was examined because previous tests<sup>3</sup> on the induction of visible sex-linked recessive mutations after larval feeding of formaldehyde have shown that approximately 50 per cent of these mutations arose as complete (or whole-body) mutations, whereas the remainder showed somatic-mosaicism for the mutation.

### The Genetical Basis for Lethal-mosaicism

One of the most objective means (and, therefore, the standard test)<sup>4</sup> for the quantitative detection of genetic

mutation in *Drosophila* is to examine for sex-linked recessive lethal mutations arising in the germinal tissue of the male. Since the male is hemizygous for the X chromosome, the male cannot be a carrier of a pre-existing sex-linked lethal, and the frequency of lethals arising 'spontaneously', or induced by treatment, can be conveniently estimated from a sample of the germ cells of the male.

The procedure used here is to mate wild-type males individually for three days to two virgin females which are homozygous for a specially-constructed X chromosome (the Muller-5 chromosome). The *F*<sub>1</sub> female progeny from this mating are consequently heterozygous for the paternal wild-type X chromosome under test and a maternal Muller-5 X chromosome: each *F*<sub>1</sub> female represents one individual wild-type X chromosome donated by one individual spermatozoon.

The *F*<sub>1</sub> female progeny (or a sample of them) arising from each male are then mated individually to an *F*<sub>1</sub> Muller-5 brother. The importance of the Muller-5 chromosome is seen here, for it contains a complex inversion which prevents crossing-over between the two X chromosomes in the *F*<sub>1</sub> female, and thus keeps the wild-type chromosome intact. The Muller-5 chromosome also carries a dominant mutation, bar-eye, and a recessive mutation, apricot eye, and these markers allow easy recognition of the two classes of male and female in the *F*<sub>2</sub> culture.

An *F*<sub>2</sub> culture without a lethal contains two phenotypically distinguishable types of male and female: thus it contains about 50 per cent Muller-5 males and 50 per cent wild-type males; and it contains about 50 per cent homozygous Muller-5 females and 50 per cent heterozygous wild-type females. (The heterozygous wild-type females, being heterozygous for the bar-eye gene, exhibit phenotypically a kidney-shaped red eye.) An *F*<sub>2</sub> culture with a lethal is detected by the complete absence of wild-type males in the culture, which also contains both types of female as well as Muller-5 males.

Since the test detects a sex-linked recessive lethal in the *F*<sub>2</sub> culture by the complete absence of males which carry the paternally-derived wild-type X chromosome, it follows that the gonad of the *F*<sub>1</sub> female carries the paternal X chromosome only in a lethally mutated condition. However, if the gonad of an *F*<sub>1</sub> female carries the paternal X chromosomes in both the non-mutated and a lethally mutated condition (that is, the female is germinally mosaic for the paternal X chromosome), then the *F*<sub>2</sub> culture may contain some males carrying the non-mutated paternal X

chromosome, and be classified as a non-lethal, or possibly as a semi-lethal, culture.

Operationally, the sex-linked recessive lethal test thus detects mutational events which produce  $F_1$  females carrying the paternal X chromosome only in a lethally mutated condition (complete lethal), and misses  $F_1$  females which are germinally mosaic for the non-mutated X chromosome and for a lethally mutated X chromosome derived from it (lethal-mosaic).

However, it is possible to detect  $F_1$  females which are germinally-mosaic for a lethal by sampling several heterozygous  $F_1$  virgin females from a non-lethal (or apparently non-lethal) culture, and mating these individually to Muller-5 males. Since each  $F_1$  female receives only one paternal X chromosome from the  $F_1$  female (which may be either non-mutated, or lethally mutated when it arises from an  $F_1$  female germinally mosaic for a lethal),  $F_1$  lethal-mosaicism is detected by the presence of both non-lethal and lethal cultures in the  $F_2$  sample from a non-lethal  $F_1$  culture. By the same procedure, it is possible to test for lethal-mosaicism in  $F_2$  females by proceeding to the  $F_3$  generation, or for  $F_2$  lethal-mosaics by proceeding to the  $F_3$  generation, and so on.

Table 1 illustrates the complete and mosaic sex-linked recessive lethal frequencies after treatment of *Drosophila* males with diethyl sulphate or formaldehyde. The  $F_2$  complete lethal frequencies are those mutations which are apparently established throughout the germinal tissue of the  $F_1$  female; the  $F_1$  lethal-mosaics are mutations occurring after a delay (from a premutational event), and are established in only a fraction of the germinal tissue of the  $F_1$  female.

The diethyl sulphate treatment is by adult feeding\* for 24 h, and the formaldehyde treatment by larval feeding on a yeast-glucose medium over the entire larval life\*; controls were by adult feeding of males in the case of diethyl sulphate, and by larval feeding of females with formaldehyde for the formaldehyde control. (Formaldehyde is not mutagenic towards female larvae.) The concentration of diethyl sulphate was adjusted to give a comparable  $F_2$  complete lethal frequency with that of formaldehyde.

Since it is usually difficult to sample from all non-lethal  $F_2$  cultures, several  $F_2$  heterozygous wild-type/Muller-5 females are collected as virgins from each of a sample of non-lethal  $F_2$  cultures, and mated individually to Muller-5 males to give the  $F_3$  generation cultures. Care was taken to sample non-lethal  $F_2$  cultures derived from each  $P_1$  male.

Details are listed in Table 1 of the number of non-lethal  $F_2$  cultures examined, and the number of males from which these are derived, the average number of females

examined from each non-lethal  $F_2$  culture, and the number of  $F_3$  cultures which later show mosaicism for a lethal in the  $F_3$  generation. The percentage of  $F_1$  lethal-mosaics is calculated from the number of non-lethal  $F_2$  cultures which yield one or more lethal cultures in their  $F_3$  sets out of the total number of  $F_2$  sets examined.

A significant increase in the frequency of  $F_1$  lethal-mosaics is observed after adult feeding of diethyl sulphate compared with the controls, while no statistically significant increase in  $F_1$  lethal-mosaics is detectable after larval feeding of formaldehyde. An increase in the frequency of  $F_2$  lethals is observed only after diethyl sulphate treatment; the formaldehyde treatments show no significant difference from the controls.

The average number of lethal cultures defining the  $F_1$  lethal-mosaics after each treatment can be estimated from the number of  $F_2$  lethal-bearing females (detected in the  $F_3$  generation). For example, the diethyl sulphate treatment gives 17  $F_1$  lethal-mosaics and there are 48 lethal-bearing  $F_2$  females distributed among them. Consequently, the average number of lethal cultures from each  $F_1$  lethal-mosaic is (48/17) or 2.8 from an average of four females from each non-lethal  $F_2$  culture (see Table 1). This figure allows an estimation of 70 per cent (2.8/4  $\times$  100) as the average mutated fraction of  $F_1$  lethally-mosaic gonads after diethyl sulphate treatment; this compared with 25 per cent for the adult feeding control, 32 per cent and 15.5 per cent for the respective formaldehyde treatments of males, and 11 per cent for the formaldehyde-treated female control.

In some cases, however, an  $F_1$  female may not be germinally-mosaic for a lethal but produce a lethal gamete spontaneously during germ cell development. Thus, if an  $F_1$  female gives one lethal  $F_2$  culture in a sample of ten, the lethal need not necessarily have arisen from a lethally-mosaic  $F_1$  gonad; only if such cases occur clearly in excess of the number expected from spontaneous mutation can they be ascribed to  $F_1$  lethal-mosaicism. In general, the more lethals present in an  $F_2$  set the less are they likely to be due to spontaneous mutation; this criterion is complicated, however, when a spontaneous mutation occurs early in germ cell development, since the resulting clone of mutant cells could be taken to be a lethal-mosaic.

It should be noted that by the larval feeding method the mutagenic activity of formaldehyde is effective through the pre-meiotic primary spermatocyte stage, and the subsequent meiotic divisions of this cell may allow the complete establishment of a mutation in the spermatozoon, even if the origin of the mutation is delayed: the higher frequency of  $F_1$  lethal-mosaics from post-meiotic stages compared with pre-meiotic stages has already been

Table 1. COMPLETE AND MOSAIC SEX-LINKED RECESSIVE LETHAL FREQUENCIES AFTER TREATMENT OF *Drosophila* MALES (AND, IN ONE CASE, OF FEMALES) WITH DIETHYL SULPHATE OR FORMALDEHYDE

reported after chemical treatments of *Drosophila* males<sup>6,7</sup>. This consideration applies only to the formaldehyde experiments, since the other types of treatment reported here are effects on spermatozoa, which require fertilization for the establishment of a mutation the origin of which is delayed.

The estimation of  $F_1$  lethal-mosaics after diethyl sulphate treatment and the adult feeding control (see Table 1) are based on small  $F_1$  sample sets (average of 4) and do not detect  $F_1$  lethal-mosaics which contain less than 25 per cent of mutant X chromosome. The  $F_1$  sets of the other treatments (Tables 1 and 2) have been increased to about ten cultures, and here the sample size does not detect  $F_1$  mosaic-gonads containing less than 10 per cent mutant X chromosome. These sampling procedures thus miss those  $F_1$  lethal-mosaics which are fractionally less than are covered by the  $F_1$  sample sets, and thus they correspondingly underestimate the frequency of mutations which occur after a delay.

The adult feeding control, the diethyl sulphate treatment, and one of the male formaldehyde treatments have been taken to an  $F_2$  generation following the same procedure described for the  $F_1$ . No significant lethal-mosaicism is detectable from  $F_2$  females either after treatment compared with the control, and none of the  $F_2$  lethal frequencies differs significantly from any other.

Since all progenies are traceable back to individual  $P_1$  males, it is possible to determine whether  $F_1$  females tend to show mosaicism for a lethal if the male from which the female is derived also gives complete lethals in the  $F_1$  generation; that is, whether the  $F_1$  lethally mosaic female comes from a lethal line or, alternatively, from a non-lethal line. The experiments presented in Table 1 are found to give lethal-mosaics only from non-lethal lines for both controls, mosaicism only from non-lethal lines in the first formaldehyde experiment, and 60 per cent mosaicism from non-lethal lines and 40 per cent from lethal lines in the second formaldehyde experiment. The diethyl sulphate treatment is found to give 37.5 per cent mosaicism from non-lethal lines and 62.5 per cent from lethal lines. All  $F_1$  'lethal-mosaics' (detectable in the  $F_2$  generation) arise from completely non-lethal lines; that is, the males gave no lethals in the  $F_1$  or  $F_2$  generations.

Table 2 lists the complete and mosaic sex-linked recessive lethal frequencies arising from *Drosophila* spermatozoa after adult feeding treatments<sup>8</sup> with ethyl methanesulphonate and *N*-nitrosomethylurea. Both compounds produce very high frequencies of complete sex-linked recessive lethal mutations, and since these frequencies represent the highest induced mutation rates yet recorded in *Drosophila*, additional data are given of the sterilities in the  $F_1$  and  $F_2$  cultures. The fertility of  $F_1$  cultures after treatment can be judged from the average number of chromosomes it has been possible to examine per male, since all females recovered from  $F_1$

cultures were examined; the control figure (10) is an arbitrary sample, since more than 10 females could have been examined per male.

Treatment of spermatozoa with either ethyl methane-sulphonate or *N*-nitrosomethylurea is found to produce lethally mosaic  $F_1$  gonads at significantly high frequencies compared with the control. The average number of lethal cultures in each  $F_1$  set is 1 for the control, 5.4 for ethyl methanesulphonate, and 6.3 and 7.3 for the respective *N*-nitrosomethylurea treatments. Both the ethyl methane-sulphonate and *N*-nitrosomethylurea treatments produce clearly significant increases in  $F_1$  lethals compared with the control.

It has so far been assumed that when more than one lethal is present in an  $F_1$  set, the lethals are identical with one another. However, this may not be true as a general rule, especially after such effective mutagenic treatments, where the possibility of two or more different delayed mutations being established in the gonad must be considered. To decide this condition, it is necessary to detect autosomal recessive lethal mutations since sex-linked recessive lethals cannot be tested for identity ('allelism').

An examination for lethal line or non-lethal line origin of lethal-mosaics in these experiments (Table 2) is found to give a non-lethal line origin for the control, and half-and-half origins for the *N*-nitrosomethylurea treatment ( $4.85 \times 10^{-4}$  M). However, the higher concentrations of the *N*-nitrosomethylurea and ethyl methanesulphonate, where all non-lethal  $F_1$  cultures were examined, gave only lethal-bearing  $P_1$  males, and all the  $F_1$  lethal-mosaics are thus from lethal lines; apparent discrepancies in the number of males tested for the  $F_1$  and in the number of males used for sampling of non-lethal  $F_1$  cultures are due to some males giving only complete lethal cultures in the  $F_1$  generation.

The misclassification of an  $F_1$  culture as a complete lethal is statistically possible, though the culture may be, in fact, either  $F_1$  lethally mosaic, semi-lethal, or even completely non-lethal. Although a complete lethal is usually confirmed by crossing a single  $F_1$  heterozygous female from the culture to a Muller-5 male, an  $F_1$  mosaic-ally lethal or a semi-lethal culture could still register as a complete lethal. Occasionally, an apparently complete  $F_1$  lethal behaves as a non-lethal on retesting; and this may well be due to the misclassification of an  $F_1$  lethal-mosaic as a complete lethal, and the chance sampling of an  $F_2$  female for retest which carries the non-mutated paternal X chromosome. Accordingly, all complete  $F_2$  lethals which occurred at the higher concentrations of ethyl methanesulphonate and *N*-nitrosomethylurea were examined for possible  $F_1$  lethal-mosaicism by sampling 20 heterozygous  $F_2$  females from each complete lethal culture. The majority of  $F_2$  complete lethals gave only lethal cultures in their  $F_2$  sets, but five cultures were

found to show mosaicism for a lethal; the  $F_1$  females from which this mosaicism arose were thus reclassified as  $F_1$  lethal-mosaics.

### The Embryological Basis of Lethal-mosaicism

Although the experiments (Tables 1 and 2) clearly show delay in the origin of sex-linked recessive lethal mutations after treatment of spermatozoa with *N*-nitrosomethylurea, diethyl sulphate, and ethyl methanesulphonate, their  $F_1$  lethal-mosaic frequencies give no real indication of the proportion of induced mutations which are expressed after a delay. Some, or even all, of the complete mutations may have arisen after a delay; that is, the mutation is not immediately established in the  $F_1$  female zygote, but occurs later in embryonic development. The gonadal tissue of *Drosophila* is derived from about three to seven cells which are situated at the posterior end of the embryo, and partitioning of these so-called pole cells to form the polar cap does not occur until about the ninth synchronous nuclear division (512 embryonic cells present)<sup>8</sup>. Since the sex-linked lethal test detects only those mutations which are present in the germinal tissue of the  $F_1$  female, a lethal may conceivably be established after a delay of several (up to about seven or eight) divisions and still be detectable as a complete mutation if the presumptive gonadal cells receive only a lethally-mutated X chromosome. Alternatively, an  $F_1$  female may be gonosomically-mosaic; that is, while carrying the non-mutated X chromosome in the gonadal cells, a lethally mutated X chromosome is present in the majority of the somatic cells. The process of gonadal embryogenesis adds a further complication to the assessment of mutational delay, since investigations on the subsequent embryonic migration of pole cells reveal that not all pole cells are incorporated into the gonad to function as primordial germ-cells, and no information is available as to a random or a non-random utilization of those pole cells (about 40 in the male, 8-12 in the female) which eventually form the gonad.

### Mosaicism for Visible Mutations

The examination of delayed germinal mutation can thus establish little in the timing or in the overall recognition of mutational delay. It would seem better to analyse such a problem by the use of visible mutations which phenotypically affect the majority of the somatic cells of the adult  $F_1$  female. Sex-linked recessive genes affecting body colour (such as yellow body) or bristle morphology (such as singed or forked bristles) when induced on a gametic X chromosome of the treated male are widely revealed in the somatic cells of an  $F_1$  female when the  $P_1$  male is crossed to a female homozygous for these genes. The induction of somatic effects involving complete mutation, or fractional mutations (such as half-and-half mosaics, quarter mosaics, etc.) can thus be used to measure the timing of mutational expression by the distribution of mutant tissue in the  $F_1$  females. However, when mutant expression is delayed more than one or

two nuclear divisions, the detection and the estimation of the fractional distribution of mutant tissue becomes difficult.

Investigations have established the whole-body character of most (93 per cent) X-ray-induced visible mutations in *Drosophila*, compared with the relatively high percentage (30/67) of fractional visible mutations arising spontaneously and after chemical treatments<sup>9</sup>; in all three series, the mutant tissue of the detected fractionals seems to involve half the body (not a quarter or less). This type of fractional mutation undoubtedly forms a large proportion of those sex-linked recessive lethals which are detected as germinally complete lethals. However, germinal-mosaicism also detects a group of delayed mutations which would not be recognized by phenotypic (somatic) effects alone. The reported absence of germinal lethal-mosaicism in *Drosophila* after X-irradiation<sup>10</sup> and after ultra-violet irradiation<sup>11</sup> of spermatozoa demonstrates the absence of a long delay in the origin of X-ray and ultra-violet induced mutation, in contrast to the prolonged delay which is found after chemical treatments.

Another consideration, arising from investigations of the induction of the autosomal visible mutation, dumpy wing (which has a restricted phenotypic distribution), after treatment of spermatozoa with a monofunctional quinacrine mustard<sup>12</sup>, is that five times as many spermatozoa carried this mutational event as would have been detected by examination of the germinal tissue alone. It has been reported<sup>1</sup> that most of the quinacrine mustard-induced phenotypic (somatic) dumpy wing-mosaics are germinally non-mutant, and this observation, besides supporting the embryological evidence that the gonad is produced from few embryonic cells, suggests that many lethal mutations must remain undetected, since they are included only in somatic tissue.

In spite of the difficulties involved in the overall assessment of delayed germinal mutation, the extension of the routine sex-linked recessive lethal test to include the detection of lethally mosaic gonads is clearly essential for a proper estimation of the effects of chemical mutagens; this consideration is of particular importance if a chemical mutagen produces a high frequency of germinal-mosaicism and a low frequency of germinally complete mutations.

I thank Prof. J. M. Thoday for supplying the laboratory facilities, and the British Empire Cancer Campaign for Research for financial support.

## PHENOLS AS PLANT GROWTH REGULATORS

By PROF. R. L. WAIN, F.R.S., and H. F. TAYLOR

Agricultural Research Council, Plant Growth Substance and Systemic Fungicide Unit, Wye College (University of London), near Ashford, Kent

THE discovery<sup>1</sup> of indolyl-3-acetic acid (IAA) as a plant growth hormone in 1934 led to the examination of compounds having a similar structure. Some of these were also found to promote cell elongation in the plant tissues used in the standard tests for growth-regulating activity, such as the wheat cylinder, pea segment, pea

curvature and tomato leaf epinasty tests<sup>2</sup>. They are active in producing morphogenic abnormalities in plants, for promoting the rooting of cuttings, for setting fruit in the absence of pollination and producing other physiological effects as does IAA. Furthermore, the more active of these compounds, for example 2:4-dichlorophenoxyacetic

acid (2:4-D) and 2-methyl-4-chlorophenoxyacetic acid (MCPA), when applied to plants at certain dose rates, were found to destroy some species and not others. Such chemicals have been developed for use in agriculture as selective weed-killers.

The important synthetic plant growth regulators fall into three groups: (a) aryloxyalkancarboxylic acids, for example 2:4-D and MCPA; (b) arylalkancarboxylic acids, for example  $\alpha$ -naphthylacetic and certain chloro-substituted phenyl-acetic acids; (c) certain halogen derivatives of arylcarboxylic acids, for example 2:3:6-trichlorobenzoic acid. Much attention has been directed to establishing relationships between chemical structure and plant growth-regulating activity for compounds within these groups. It is of interest that substitution of chlorine into the 2- and 6-positions in the ring of phenoxyacetic acid confers only slight growth-regulating activity, whereas similar substituents with phenylacetic and benzoic acids give compounds with high activity<sup>3,4</sup>. Several theories attempting to account for such behaviour have been suggested.

Compounds outside the foregoing three groups have also been shown to exhibit growth-regulating activity. These include simple molecules such as ethylene, propylene and acetylene, and certain dithiocarbamate derivatives<sup>5</sup>. A number of other unrelated substances show slight activity in the wheat cylinder test. Since this activity is only evident at concentrations just below those which produce toxic symptoms, these compounds are not regarded as true growth substances. Their apparent activity could arise from damaging effects on the cell-wall which lead to changes in its plasticity<sup>6</sup>.

Among phenolic compounds, *trans*-caffeic acid was reported by Vendrig and Buffell<sup>7</sup> to be active in the *Avena* coleoptile test, but Thimann *et al.*<sup>8</sup> found it possessed negligible activity in this test and was inactive in the pea curvature test; we have shown it to be inactive in the wheat cylinder, pea segment and pea curvature tests. The compound acted as a synergist, however, when tested with IAA (ref. 8) as did a number of other phenolic compounds examined by Nitsch and Nitsch<sup>9</sup>.  $\alpha$ - and  $\beta$ -Naphthols have been reported to be slightly active in promoting rooting of cuttings of *Phaseolus vulgaris*<sup>10</sup>.

Work by one of us led in 1959 to the discovery of a new highly effective contact herbicide, 3:5-diiodo-4-hydroxybenzonitrile, which was given the common name 'ioxynil'<sup>11</sup>. Since that time, the compound has received considerable attention here, and much is now known of its mode of action. In a study of analogues, 2:4:6-triiodophenol, in which the nitrile group of ioxynil is replaced by iodine, was examined. The compound was found, over some weeks, to produce morphogenic effects in tomato plants when added to the soil in which they were growing. Since this was a response similar to that induced by synthetic plant growth-regulating substances, we decided

to make a systematic investigation of halogen-substituted phenols as growth substances. It has now been found that some of these molecules are markedly active in this respect.

Phenol itself,  $\alpha$ - and  $\beta$ -naphthol, and all the chloro- and dichloro-phenols were first examined in the wheat cylinder, pea curvature, pea segment, and tomato leaf epinasty tests. All were inactive with the exception of 2:6-dichlorophenol. Solutions of the sodium salt of this compound were active in the wheat cylinder test and highly active in the two pea tissue tests (Table 1). In the tomato epinasty test when applied at 2 per cent in lanolin a strong and typical growth-substance response was obtained.

Further experiments with trichloro-, tetrachloro- and pentachloro-phenols revealed the known high phytotoxicity of these compounds; 2:3:6-trichlorophenol, however, was found to possess significant growth-regulating activity (Table 1). The relatively unstable 2:6-dichlorothiophenol was slightly active, but 2:6-dibromophenol showed high, and the 2:6-diiodophenol very high, activity in the pea and tomato tests (Table 1); 2:6-dimethyl- and 2:6-dinitrophenols and 2-chloro-, 2-bromo- and 2-iodo-phenols were all inactive.

Within 24 h of the application of solutions of 2:6-dichloro-, dibromo- or diiodo-phenols to the soil of potted tomato plants, severe epinastic responses were obtained. This reaction was particularly severe and persistent with the dibromo- and diiodo-compounds; plants treated with the dichloro derivative in this way tended to recover after some days.

As with the benzoic and phenylacetic acids which show growth-promoting activity, these active phenols possess a weakly acidic grouping with two *ortho*-substituted halogen atoms in the ring. The pattern of activity exhibited by these phenols, however, is of interest in that the compounds are much more active in the pea curvature and pea segment tests than in the wheat cylinder test (Table 1), a type of behaviour which is not usually observed with synthetic plant growth-regulators. On the other hand, there are further similarities between the benzoic acids and phenols. In the 2:6-disubstituted benzoic acids, the activity is removed when a *para* substituent is introduced<sup>3</sup> and our results indicate that this same structural requirement operates also with phenols. Thus, 2:6-dichloro- and dibromo-phenols are active in the wheat and pea tests and 2:4:6-trichloro- and tribromo-phenols are inactive. Again, while 2:6-diiodophenol is active in these tests, substitution of OH, I, NO<sub>2</sub>, CN or COOH in the 4-position destroys activity completely. These and other observations indicate that phenols and benzoic acids may have a similar mode of action in plant growth regulation.

In view of the extensive investigations which have been carried out on plant growth substances during the past thirty years, the high activity of certain halogen-substituted phenols, here reported, must be regarded as an important

Table 1. GROWTH-REGULATING ACTIVITY OF CERTAIN HALOGEN-SUBSTITUTED PHENOLS ASSESSED IN THE WHEAT CYLINDER, PEA SEGMENT AND PEA CURVATURE TESTS

Compound	Test	Concentration $\times 10^{-4}$ molar

## REACTION OF AMINO-ACIDS AND PEPTIDE BONDS WITH FORMALDEHYDE AS MEASURED BY CHANGES IN THE ULTRA-VIOLET SPECTRA

By PROF. LEO. J. SAIDEL, JOEL S. SATZMAN and WILLIAM H. ELFRING, jun.

Department of Biochemistry, Chicago Medical School

AS part of an investigation of cross-links produced in proteins by formaldehyde<sup>1</sup> it was observed that solutions of proteins, peptides and amino-acids exhibit appreciable changes in their ultra-violet spectra in the 210–250 mμ range when formaldehyde is added to them<sup>2</sup>. Since the observation of Einhorn<sup>3</sup> that the *N*-alkyl amides of fatty acids are very unreactive, it has been generally accepted that the peptide bonds of proteins react with formaldehyde very slowly or not at all<sup>4,5</sup>. The observed spectral changes demonstrate that the peptide bond of certain peptides can in fact react with formaldehyde and suggest that similar reactions can occur in proteins. Fraenkel-Conrat and Oloott<sup>6,7</sup> have accumulated considerable evidence to prove that many side-chain groups can react. And although model investigations have indicated that some of these reactions are also accompanied by spectral changes<sup>8</sup>, this article will be limited to consideration of reactions involving only amino-groups, unsubstituted amido-groups and substituted amido or peptide-groups.

To force the reactions to equilibrium in a reasonable period of time and to minimize reactions among the molecules of the compounds themselves, high formaldehyde concentration (3 M) somewhat elevated pH (pH 10) and temperature (40° C) and very dilute amino- or amido-solutions (0.0005–0.001 M) were chosen initially. However, many measurements were also made at 25° C and at lower pH. Reagent grade formalin containing 37.1 per cent formaldehyde and 14 per cent methanol was diluted to the proper concentration before use. Formalin containing less than 1 per cent methanol, supplied by the Celanese Chemical Co., was found to give essentially the same results when tested in some of the reactions, although the rates were somewhat elevated. All reactions were carried out in buffered solutions: 0.02 M borate buffer above pH 8 and 0.038 M phosphate buffer below pH 8.

Absorbance changes at 220 mμ and constant temperature were followed with either a Beckman model DU or a time-driven model DK-2 spectrophotometer. The absorbance at 220 mμ of 3 M formaldehyde is not too high with the buffers used if the pH is kept below 10.5. Above pH 10.5 the much more highly absorbing anionic formaldehyde exists in appreciable concentration and readings must be made at longer wave-length with higher compound concentration. To compensate for changes in the absorption of the formaldehyde on standing, both reference and sample cuvettes always contained equal concentrations of formaldehyde initially. Some minor errors in the early report<sup>1</sup> attributable mainly to this effect are corrected here.

**Reactions of mono- and di-amino-acids with formaldehyde.** The addition of formaldehyde to neutral or alkaline solutions of free amino-acids at 40° C has the immediate effect of increasing the absorptivity 2–3-fold (Figs. 1 and 2), the increase depending on the concentration of

formaldehyde, the pH and the structure of the amino-acid. Glycine and threonine behave like the amino-acids indicated in Fig. 1. The increase may be reversed by acidifying the solutions to pH 1–2 whereupon the absorptivity drops to that of unassociated cationic amino-acid. It is usually assumed that reaction of formaldehyde with amino-acids is nearly instantaneous, but Baur<sup>9</sup> reported an initial change in conductivity lasting for as long as 2 min when glycine was mixed with formaldehyde. If absorptivity measurements are made rapidly at 25° C, the results indicated in Fig. 1 (inset) are obtained.

In harmony with the theories of Levy and Silberman<sup>10</sup> explaining their titration curves the initial rapid increase is attributed to monomethylolamine formation, while the subsequent decrease observed at higher formaldehyde concentrations to dimethylolamine formation. If the Levy-Silberman<sup>10</sup> theory regarding the reaction of formaldehyde

Fig. 1. Molar absorptivity changes at 220 mμ produced by the reaction of formaldehyde with mono- and di-amino acids. All curves on the large graph were obtained at 39 ± 1° C and 3 M formaldehyde at pH 9.5 with 0.001 M amino-acid. The 6-aminocaproate points are crosses (x), the L-2,4-diaminobutyrate points solid squares (■), the L-2,3-diaminopropionate points solid triangles (▲), the L-lysine points dotted circles (○), the L-proline points solid circles (●). The points to the left of the graph represent the absorptivity values before the addition of formaldehyde; the points to the right of the graph represent the absorptivity values when the reaction has reached equilibrium. In a few instances a small correction is made for a much slower secondary reaction. The numbers under the curves are apparent first-order reaction rate constants in units of min<sup>-1</sup>. The curves in the inset were obtained at 25° C with 0.001 M L-leucine at the indicated formaldehyde concentration in 0.02 M tetraborate buffer at pH 9.7 ± 0.3.

with primary amino-groups is accepted, it is possible to calculate, from this and previously published data<sup>8</sup>, the association constants of the amino-group with one and two molecules of formaldehyde, and to assign absorptivity values to the monomethylolamine and dimethylolamine respectively.

Like the monoamino-acids, the diamino-acids exhibit the initial changes in absorption with formaldehyde attributable to mono- and di-methylolamine formation. But in addition they exhibit a secondary change much slower even at 40° C than any observed with monoamino-acids (Fig. 1). Apparent first-order kinetics is obeyed throughout most of this phase of the reaction. French and Edsall<sup>4</sup> have suggested *N,N'*-methylene bridge formation for lysine. And although no attempt has been made to isolate any of the reaction products, the present observations lend some support to this possibility: (1) First-order kinetics for the secondary change is consistent with an intramolecular rather than an intermolecular reaction. (2) Unlike methylolamine compounds the lysine-formaldehyde reaction product does not return to an unassociated state at pH 1-2. This is indicated by an absorptivity value of about 400 for the acidified reaction solution instead of an expected value of about 50 for unassociated dicationic lysine and also by the very rapid return to high absorptivity on re-alkalinization. (3) The observed rate constants appear to correlate to some extent with the expected probabilities of formation of an 8-membered ring with lysine, a 6-membered ring with 2,4-diaminobutrate and a 5-membered ring with 2,3-diaminopropionate.

**Reaction of unsubstituted amides with formaldehyde.** Unlike amino-groups, unsubstituted amido-groups exhibit only a slow increase in absorption with formaldehyde at pH 10 represented by curves for acetamide and *N*-acetylaspargine in Fig. 2. At the high formaldehyde concentration used the reaction obeys apparent first-order kinetics. There is a strong pH dependence indicated

Fig. 2. Molar absorptivity changes at 230 m $\mu$  produced by the reaction of 3 M formaldehyde with unsubstituted amide groups. All reactions were carried out at either 20.3  $\pm$  0.7° or 24.7  $\pm$  0.8° C represented by broken lines and at either pH 9.0  $\pm$  0.3 represented by solid symbols or pH 6.0 represented by open symbols. Here the acetamide points are stars, the *N*-acetyl-L-asparagine points are diamonds, the L-asparagine points are squares, the L-glutamine points are circles, and the glycine points are triangles. As in Fig. 1 the points to the left of the graph represent the absorptivity values before addition of formaldehyde; the points to the right of the graph represent the absorptivity values when the reaction has reached equilibrium. The numbers under the curves are apparent first-order reaction rate constants in units of min<sup>-1</sup>.

by the absence of absorption change of *N*-acetylaspargine at pH 7 (Fig. 2) within 20 h. However, unlike the reaction of formaldehyde with the amino-group, the reaction with the amido group is not reversed by lowering the pH. Methylolamide formation by reaction of formaldehyde with acid amides has been known since the early researches of Einhorn<sup>9</sup> *et al.* using preparative procedures. Later Crowe and Lynch<sup>10</sup> using a polarographic method found that the reaction is second order for amide and formaldehyde concentrations, greatly increases in rate when the pH is varied from 8.6 to 12.7, and yields an association constant of about 25 over the entire pH range already indicated here. It is fairly certain that the absorption increase observed at pH 10 (Fig. 2) is caused by methylolamide formation.

The amino-acid amides treated with formaldehyde at pH 10 exhibit both the rapid initial increase in absorption characteristic of amino-groups and the slow subsequent increase characteristic of amido groups (Fig. 2). But at pH 7 only asparagine and glutamine exhibit the slow reaction whereas glycine does not (Fig. 2). From the disappearance of nitrous acid reactive groups and measurement of pH changes Levy and his colleagues<sup>11</sup> have concluded that asparagine and glutamine undergo rapid mono- and di-methylolamine formation, followed by slow methylolamide formation and *N,N'*-methylene bridge ring closure. Their results indicate that methylolamide formation limits the subsequent rate of ring closure. It is possible that the absorption changes observed at pH 7 indicate that asparagine and glutamine can form the *N,N'*-methylene bridge whereas glycine cannot. In any event, methylolamide formation does not appear to be the rate-limiting step because *N*-acetylaspargine, which has a free amido group, fails to react at pH 7. No explanation is at hand for the much greater reactivity of glutamine compared with asparagine.

**Reaction of *N*-alkyl substituted amides with formaldehyde.** The change in absorption observed with certain substituted amides, for example *N*-methylacetamide and *N*-acetyl glycine (Fig. 3), is similar to that observed with unsubstituted amides. On the other hand, the immediate increase observed with glycine anhydride is different (Fig. 3). It was erroneously stated earlier that glycine anhydride exhibits no change in spectrum<sup>4</sup>. Presumably the products of all these reactions are methylolamides. This conclusion is in agreement with those of other laboratories based on preparative methods starting with glycine anhydride<sup>12</sup> and *N*-methylacetamide<sup>13</sup> and measurement of bound formaldehyde<sup>14</sup>, but is contrary to that of Einhorn<sup>9</sup> already mentioned. The strong dependence of the rate of the reaction on pH may be seen by comparing the curves for *N*-acetyl glycine at pH values of 10 and 7 in Fig. 3. However, above about pH 9, where the reaction occurs at a readily measurable rate, the completeness of the reaction, as measured by the equilibrium absorptivity, appears not to depend on pH. Both the rate of attaining equilibrium and the completeness of the reaction do depend on formaldehyde concentration. Thus, the rate constants in Figs. 2 and 3 are only approximately comparable because, when the measurements were made, the importance of precise pH control was not realized. By measuring the equilibrium absorptivity at more than one concentration of formaldehyde, it is possible to calculate both the absorptivity of the methylolamide and the equilibrium constant of the reaction. None of these reactions is reversed by lowering the pH.

The effect of the *N*-alkyl substituent on the equilibrium point was determined by comparing the reactivity of various *N*-acetyl amino-acids. Unlike *N*-acetyl glycine, the *N*-acetyl derivatives of leucine (Fig. 3), alanine and glutamic acid exhibit only a slight rise in absorptivity at pH 10 or even higher. For the reaction to approach completion, two or more hydrogen atoms are required on the alkyl carbon atom bonded to the nitrogen atom. There is further evidence for this in the appreciable

Fig. 3. Molar absorptivity changes at 220 m $\mu$  produced by the reaction of 3 M formaldehyde with substituted amide groups. The *N*-acetyl-glycine points are squares, the *N*-acetyl-L-leucine points hexagons, the *N*-acetyl-L-leucylglycine points triangles, the glycine anhydride points diamonds, the glycylglycine points circles, the glycyl-L-leucine points ellipses, the L-leucylglycine points double triangles ( $\nabla$ ), the *N*-methyl-acetamide points stars. As in Fig. 1 the points to the left of the graph represent the absorptivity values before addition of formaldehyde, the points to the right of the graph represent the absorptivity values when the reaction has reached equilibrium. The numbers under the curves are apparent first-order reaction rate constants in units of min<sup>-1</sup>. As in Fig. 2 the reactions were carried out at either 30  $\pm$  0.7° C represented by solid lines or 24.7  $\pm$  0.3° C represented by broken lines and at either pH 9.9  $\pm$  0.8 represented by solid symbols or pH 6.9 represented by open symbols.

increase in absorptivity observed when the *N*-acetyl derivatives of  $\beta$ -alanine and 6-aminocaproic acid are treated with formaldehyde at pH 10. The increase in absorptivity observed with *N*-acetylleucylglycine at pH 10 (Fig. 3) can then be explained in terms of appreciable methylation of the *N*-leucyl bond but not the *N*-acetyl bond.

The true peptides, possessing a terminal amino-group, may or may not exhibit the initial increase in absorption depending on the relative absorptivities of the dimethylol-amino and monomethylolamino derivatives and the concentration of formaldehyde. The slow subsequent increase observed with some of the *N*-acetyl amino-acids is likewise observed with the corresponding peptides. Thus, glycylglycine like *N*-acetylglycine undergoes a slow increase to

high absorptivity at pH 10 and appears not to react appreciably at pH 7 within 20 h (Fig. 3). Similarly, leucylglycine (Fig. 3), alanyl-glycine<sup>1</sup> and prolylglycine<sup>12</sup> all undergo slow increases to high absorptivity at pH 10. Glycylleucine, on the other hand, like *N*-acetylleucine, exhibits only a slight increase in absorptivity at pH 10 (Fig. 3). Of course, glycylproline with no replaceable hydrogen on the peptide bond nitrogen exhibits only the initial increase in absorptivity but no subsequent increase<sup>1</sup>.

With the examination of more peptides and with the great prolongation of the period of observation at different pH levels (see legend to Fig. 3) the parallel behaviour of peptides and *N*-acetyl amino-acids begins to disappear. The *N*-terminal amino-group, the side-chains on the acyl residues of the peptide and the length of the peptide chain all affect the reactivity of the peptide bonds in a discernibly systematic way, particularly at pH 7. The formation of a methylene bridge between the amino-nitrogen and a peptide-nitrogen has been suggested by French and Edsall<sup>4</sup>. Their suggestion was based in part on the work of Wadsworth and Pangborn<sup>14</sup>, who demonstrated the irreversible bonding of formaldehyde coupled with the disappearance of amino-nitrogen when alanyl-glycine was treated with 1 mole of formaldehyde at pH 8. The spectrophotometric studies lead to a similar conclusion. The complete evidence is based on the examination of a large number of additional peptides and is beyond the scope of this article. However, the results presented here clearly demonstrate that peptide bonds react with formaldehyde and provide some basis for concluding that part of the absorption change observed with insulin<sup>3</sup> and other proteins, including gelatine on formaldehyde treatment<sup>15</sup> is attributable to the reaction with certain peptide bonds.

We thank Mr. Joe DeBlasi for his assistance. This work was supported by the U.S. Office of Naval Research, contract Nonr 1655(01), (NR-304-303) and by the U.S. National Institutes of Health, grant GM-09434.

## BROAD-BANDED STRIATED BODIES IN THE SENSORY EPITHELIUM OF THE HUMAN MACULA AND IN NEURINOMA

By PROF. I. FRIEDMANN, SIR TERENCE CAWTHORNE and MR E. S. BIRD

Department of Pathology, Institute of Laryngology and Otology, London

IN a recent publication Lowenstein and Osborne<sup>1</sup> described an interesting striated structure in the sensory hair cells of the labyrinth of the ammocoete larva of the lamprey, *Lampetra fluviatilis*. The authors have suggested that no such organelles have been described in the labyrinth of any other animal and a brief description of our own findings in the human labyrinth and elsewhere might be of some interest.

We have studied eleven specimens of the human utricle removed at operation to cure Ménière's disease. The

specimens were promptly fixed in iced buffered osmic acid in the first three cases and embedded in methacrylate, and in 4-5 per cent buffered glutaraldehyde<sup>2</sup> in the next eight cases, then embedded in 'Araldite'<sup>3</sup>. Ultra-thin sections were cut on a Huxley-type ultramicrotome, stained with Karnovsky's lead monoxide and examined under a Siemens Elmiskop I electron microscope.

There was more or less widespread degeneration affecting many cells of the macula showing vacuolation of the cytoplasm and large numbers of fat droplets. Moreover

Fig. 1. Degenerating cell of human macula (Ménière's disease) with large numbers of fat droplets (F). Note laminated inclusion (LI) ( $\times 16,800$ )

the cup-shaped nerve endings of Wersäll embracing the degenerating hair cells have undergone degenerative changes affecting both the numerous mitochondria and the nerve tissue proper. Such calyces appeared as darkly stained rings round cross-cut hair cells. The surface was usually covered with some amorphous degenerated cellular matter in which there were embedded remnants of the ciliary apparatus extensively damaged in all cases.

Two unusual structures have been observed: (a) intracellular laminated structures, (b) extracellular broad-banded filaments (? long-spacing collagen).

**Laminated structures.** These are polygonal or rhomboid crystalline structures 0.5–1.5  $\mu$  wide, formed by alternating dark and less dark lines (Fig. 1). The dark lines or bands are 100 Å wide and repeat approximately every 1,000–1,500 Å to form a macroperiod. Each major period is subdivided by a less dense line or band about 70–80 Å wide and they may be linked by thin fibrils.

The common site of the crystalline inclusions found in eight specimens (Table 1) seems to be the apical and perinuclear zones of the hair cells. There are, however, similar striated structures within the cuticle close to the rootlets of the stereocilia where their position suggests some functional association with the cilia. The inclusions may be present in well-preserved cells, but more frequently

appear to be associated with fat droplets, degenerating mitochondria or some amorphous matter probably of cytoplasmic origin. The inclusions may be single or form groups (Fig. 2), especially in degenerated parts of the epithelium where numerous laminated structures grouped together often form a 'parquet-floor' pattern (Wetzstein *et al.*<sup>4</sup>).

**Broad-banded filaments (long-spacing collagen 'Luse body').** Apart from the laminated inclusions, broad-banded filaments were seen in five specimens (Table 1) underneath the basement membrane of the neuroepithelium closely associated with myelinated nerve fibres (Fig. 3) or scattered between the numerous non-myelinated nerve axons of the utricular branch of the vestibular nerve. The broad-banded filaments form long chains or fusiform bodies. The intervals between the bands measure approximately 1,000 Å. There is little similarity between these extracellular filamentous structures and the intracellular laminated material described here. The long-spacing fibres are particularly abundant among the terminal branches of the vestibular nerve itself and can readily be distinguished from native collagen.

**Neurinoma (neurilemmoma).** Similar striated filamentous structures may be found in some tumours arising from Schwann cells. We have found numerous striated fusiform structures in thin sections of a neurilemmoma presenting as a nasal polyp (Fig. 4) similar to those first described in neoplasms of the eighth nerve by Luse<sup>5</sup> and by Raimondi *et al.*<sup>6</sup>; and more recently by Pillai<sup>7</sup> in the experimentally constricted tibial nerve of rats. The fusiform or comma-shaped striated bodies in the nasal tumour are closely associated with the basement membrane and seem to emerge from it.

Unusual laminated or striated structures have been described in various tissues by several authors; some of them are listed in Tables 2 and 3.

tolerated by the membrane. Only those were used which brought down the resistance to 10 per cent of the starting value within 5-10 min.

Fig. 1 illustrates a typical experiment in which an anionic detergent developed a cationic resting membrane potential. Addition of the detergent lowered the initially high resistance by several decades. The input impedance was kept high in all cases with respect to the total membrane resistance, so that the potential was accurately recorded. The experiments were followed by controls to rule out potentials generated by the detergents themselves without a salt gradient. To exclude the effect of H<sup>+</sup>-ions the pH was adjusted before and tested after every experiment. No deviation from the adjusted buffer value was detected.

All four types of detergents lower the membrane resistance and develop potentials to varying degrees, at least transiently. Only the anionic detergents produce prolonged steady effects. It may be noted that amphoteric detergents could only be tested at a pH close to 6.8, since the membranes tended to break at higher values. The isoelectric points of these amphoterics usually lie far on the acidic side and so they only showed anionic properties. No qualitative difference in their behaviour from anionic detergents could be found.

All the detergents in the concentrations listed in Table 1 decreased the membrane resistance within a few minutes by at least 10<sup>3</sup> ohms. In the case of anionics and cationics the resistance stayed at low values or continued to decrease slowly during experiments that lasted for more than 1 h. The initial decrease of resistance produced by non-ionics, however, was followed in turn by a spontaneous increase, the resistance approaching the original high state again within minutes. This transient action apparently depended on the concentration of detergent used: the higher the concentration, the slower the lowered resistance reversed.

Potential differences across the membrane are produced by detergents in two ways: (a) there are potentials generated by the detergents themselves in the absence of additional salt gradients; (b) there are potentials generated by the detergents by virtue of an additional salt gradient.

All types of detergent produced potentials of varying magnitude, *per se*, in the absence of a salt gradient. The sign of these potentials was the same as the sign of the detergent molecule itself and not the sign of its counterion, non-ionic detergents acting like anionic detergents. Thus, anionic and non-ionic detergents showed a small anionic potential immediately after adding them to the system. This potential was small and did not exceed 4 mV; it decayed within seconds. On the other hand, cationic detergents developed a large cationic potential, *per se*, which increased with increasing concentration of the detergent and persisted for some time. For example, cetyl-pyridinium chloride in a final concentration of 10<sup>-2</sup> per cent w/v developed a cationic potential of 50-60 mV in a few minutes, which steadily decayed to zero over 5-10 min.

In the presence of a salt gradient (high concentration inside) anionic and non-ionic detergents generated a cationic potential. Only with anionics did a steady potential difference persist across the membrane, in many experiments for more than 1 h. The potential generated

Fig. 2. Potential as function of KCl gradient. O, 'Ultrawet KX' (anionic),  $5 \times 10^{-3}$  per cent w/v final concentration, ●, 'Pluronic L 101' (non-ionic),  $4 \times 10^{-4}$  per cent v/v final concentration.

by non-ions in the presence of a salt gradient decayed within 20–60 min as the membrane resistance recovered. By contrast, cationic detergents lowered the membrane resistance considerably, but no potential difference was produced by a salt gradient. Introduction of a gradient during and after all phases of the self-generated cationic potential remained without additional effect on the potential. The potential developed across the membrane as a function of a salt gradient is shown in Fig. 2 for an anionic and a non-ionic detergent.

Saponin, a surface-active molecule with haemolytic activity, was found to act like an anionic detergent in a concentration of  $5 \times 10^{-3}$  per cent w/v.

The mode of action of detergents on lipid bilayers as described herein could be explained as a modification of the lamellar membrane structure by a phase transition to localized 'micellar' arrangements (cf. ref. 7). The structure of the membrane is sufficiently flexible to adopt these different configurations. The 'liquid' state of the lipid hydrocarbon chains in the lamellar phase<sup>8</sup>, that is, their

relatively free mobility, would permit the rearrangement of the lipid membrane structure. Localized lipid micelles with a negative charge would result and form a fixed-charge, cation-selective pore of the Teorall-Meyer-Sievers type. The degree of vibrational freedom across the bilayer of the 'fixed' sites (that is, restricted to the lipid phase) is unknown. If great enough, the fixed sites would become carrier-like.

This hypothesis could serve as a model for the specialized lipid-protein interaction developing channels in cell membranes. Proteins, for example, EIM, with their surface-active properties<sup>9</sup>, might modify the molecular configuration of the lipid membrane in a similar way as proposed for detergents. An illustration of such a hypothesis was recently given by Trams<sup>10</sup>.

Further investigations of molecularly defined surfactants with synthetic unsaturated lipid membranes may lead to information as to the atomistic arrangements of structural units in the cell membrane during different functional states.

I thank Dr. P. Mueller and Dr. D. O. Rudin for their advice. I also thank the chemical companies mentioned herein for their help in providing the detergents used in this investigation.

## VARIATIONS IN PHOSPHOKINASE ACTIVITIES DURING THE CELL CYCLE IN SYNCHRONOUS POPULATIONS OF HELA CELLS

By T. P. BRENT, PROF. J. A. V. BUTLER, F.R.S., and DR. A. R. CRATHORN

Chester Beatty Research Institute, Institute of Cancer Research, Royal Cancer Hospital, Fulham Road, London, S.W.3

KNOWLEDGE of the sequence of events in the replication cycle of mammalian cells would be of great importance in elucidating the control mechanisms involved. Up to the present, the process which has been most investigated in this connexion is the synthesis of DNA, which has been found to occur continuously between divisions in bacteria<sup>1</sup> but is restricted to the so-called S-phase in mammalian cells. Few observations have been made of the events in the cell cycle such as the levels of particular enzyme activities. The enzymes involved in the production of the immediate precursors of DNA synthesis are of special interest and have been widely studied in asynchronous cell populations, for example, the thymidine phosphokinase reactions:

which we have now examined in a synchronously dividing population of HeLa cells. For the purposes of the work recorded here, reaction 2 was taken as a single reaction, since, although the diphosphate has been shown to be an intermediate in some cell systems<sup>2</sup>, under the conditions

of assay used the formation of the diphosphate as a precursor of the triphosphate could not be detected.

The difficulty in examining these reactions at various stages in the cell cycle has been that of obtaining a homogeneous synchronous population of cells in sufficient quantity for the assay of these enzymes. Some previous work on the changes of level of the thymidine phosphokinases has been carried out using regenerating rat liver<sup>3</sup>; however, this tissue is unsatisfactory since less than 10 per cent of the cells take part in the burst of cell division following hepatectomy. Synchrony in mammalian cells has been obtained by a number of different methods<sup>4</sup>. In most of these, induction of synchrony is accompanied by a metabolic disturbance to the cells and may result in unbalanced growth of the culture. The technique of selecting cells from a randomly dividing population does not appear to be open to this criticism.

In the investigation reported here a reasonably synchronous population was obtained, in sufficient quantity for enzyme assay, by a method essentially that of Robbins and Marcus<sup>5</sup>. Mitotic cells were selected by washing a monolayer culture with Eagle's medium deficient in  $\text{Ca}^{++}$ . The cells were routinely grown as monolayers and in

Fig. 1. Synchronous growth of HeLa cells through one division cycle after collection of mitotic cells at zero time. Cell number (.....) was measured by haemocytometer. The rate of DNA synthesis (●—●), given as c.p.m. in DNA, was determined by the incorporation of tritiated thymidine at each time by an aliquot of cells during a 15-min pulse. Thymidine phosphokinase activity (○—○), given as  $\mu$ moles TdR phosphorylated/h/10<sup>4</sup> cell equivalent, and thymidylate phosphokinase activity (□—□), given as  $\mu$ moles TMP phosphorylated/h/10<sup>4</sup> cell equivalent, were determined in the supernatant fractions.

suspension in Ca<sup>++</sup>-deficient Eagle's medium supplemented with 5 per cent pig serum and 2 per cent calf serum.

The degree of synchrony was determined by measuring the mitotic index of a stained preparation of cells at the time of collecting. This varied from 50 to 85 per cent. The cell number was followed during the subsequent cycle by counting cells in selected fields on Petri dishes<sup>4</sup> or by haemocytometer counting (Fig. 1).

The rate of DNA synthesis throughout the cell cycle was measured in two ways. First, by scoring the percentage of cells labelled in autoradiographs of coverslip cultures which had been pulsed with tritiated thymidine. Secondly, cells in suspension were pulsed with tritiated thymidine and then collected on 'Millipore' filters under suction, washed with about 20 ml. of phosphate-buffered saline and fixed by washing with a similar volume of 5 per cent trichloroacetic acid. The filter was then dissolved in scintillation liquid and counted in a Packard liquid scintillation counter. The incorporations thus measured were in good agreement with measurements of incorporation of tritiated thymidine into the hot trichloroacetic-soluble material of the cell. The curves for the rate of DNA synthesis during the cell cycle are similar to those described by Terasima and Tolmach<sup>7</sup> (Fig. 1).

For enzyme assays, 2–3 × 10<sup>7</sup> synchronous cells were maintained in magnetically stirred suspension throughout a complete cell cycle. Aliquots of the suspension, equivalent to 2–3 × 10<sup>4</sup> cells, were taken at intervals for preparation of an enzyme fraction. The cells were washed in ice-cold phosphate-buffered saline and then in a sucrose-potassium chloride medium at pH 8 (ref. 8) prior to sonication in a small volume (0.5 ml.) of the latter. The supernatant fraction obtained by centrifuging at 100,000g for 40 min was stored at –20°C and used for enzyme assays.

Thymidine kinase was assayed by incubating 0.05 or 0.1 ml. of the supernatant for periods up to 1 h at 37°C with an equal volume of an incubation medium containing 10 mM ATP, 10 mM MgCl<sub>2</sub>, 12 mM 3-phosphoglycerate and 160 mM tris-HCl, and about 700  $\mu$ moles tritiated thymidine of high specific activity (14 c./mmole, Radiochemical Centre, Amersham). The reaction was stopped by adding 100 per cent w/v trichloroacetic acid to a final concentration of 10 per cent. 20  $\mu$ l. of the supernatant, containing the phosphorylated products of thymidine, was chromatographed on Whatman No. 1 paper, using a

solvent system comprising butanol, acetone, acetic acid, ammonium hydroxide. The distribution of the phosphorylated derivatives was measured using a Nuclear Chicago windowless chromatogram scanner.

The percentage conversion of thymidine to TMP and TTP was plotted against incubation time—the slopes of these plots being taken as the relative enzyme activities of the supernatant preparations at different times during the cell cycle.

It was found that the level of thymidine phosphokinase (reaction 1) is low immediately after division (G1 phase), rises during the S period, reaches a maximum about 5 h after the peak of DNA synthesis and falls rapidly during the subsequent division (Fig. 1). The curve of activity for the thymidylate phosphokinase (reaction 2), assayed by substituting tritiated TMP for tritiated TdR in the substrate, is similar to that for thymidine phosphokinase. Preliminary assays have also shown a similar pattern for deoxycytidine phosphokinase.

These results show conclusively that the thymidine phosphokinases go through a sequence of appearance and disappearance during the cell cycle as assayed in the supernatant. The peak in enzyme activity occurs somewhat later than the peak of DNA synthesis as was also found in the case of regenerating liver<sup>8</sup>. Since these enzymes must have been present in sufficient quantity in the cell at the beginning of the S period, in order to produce the precursors required for DNA synthesis, it must be concluded that they are present in the cell, at such times, in a form which is not apparent on assay of the enzyme activity in the supernatant.

Two possible explanations of this finding can be suggested: (1) The enzymes are present before and during DNA synthesis in the form of a complex with the nuclear particulate fraction of the cell, and the observed increase in activity represents their release to the supernatant fraction when their function has been completed. (2) The observed increase in activity is due to actual enzyme synthesis and the subsequent decrease due to the binding of this enzyme to a nuclear particulate fraction, preparatory to its functioning in the next cell cycle. Such a mechanism has been postulated by Maxia<sup>9</sup> for DNA polymerase in embryos of sea urchins.

However, it has been shown for several cell systems that the lifetimes of the phosphokinases in the cell are considerably less than one cell cycle<sup>10</sup>. It therefore seems more probable that these enzymes will be formed shortly before they are to be used by the cell. In order to distinguish between these two hypotheses it will be necessary to determine whether the rise in enzyme-levels observed (Fig. 1) is due to new protein synthesis at this time or at some earlier stage, information which can only be obtained indirectly on the small samples available. These possibilities are being further examined.

## LETTERS TO THE EDITOR

## RADIO ASTRONOMY

## Radio Brightness Contours of 3C273

PREVIOUS observations of the radio source 3C273 by the method of lunar occultations have shown that it consists of two separate components the positions of which were determined with an accuracy of 1 arc sec<sup>1</sup>. Component *A* coincides closely with a jet-like nebula and component *B* with a nearby object of stellar appearance<sup>2</sup>. This communication presents a contour map of the source, constructed from the analysis of five complete occultations.

The observations were made with a parabolic antenna 85 ft. in diameter, which tracked the source position for the duration of the occultation. The receiver was a switched type, without image rejection, operating at a frequency of 950 Mc/s. Its intermediate frequency was 30 Mc/s, band-width 5 Mc/s, and noise figure 3.6 dB. Figs. 1*a* and *b* show analogue records of the emission and immersion of the source at one occultation. The output time constant was 1 sec for all observations except for the data reproduced in Fig. 1.

Table 1 lists the dates of the occultations and the position angles at which they occurred. The position angle indicates the direction in which the Moon's limb advanced or receded across the central region of each component. The records were analysed on a digital computer with a programme<sup>3</sup> based on the restoration process of Scheuer<sup>4</sup>. This programme convolves the observed data with a restoring function and derives the brightness distribution as it would be observed with a gaussian fan beam scanned over the source along the position angle of the occultation. The observations were all restored with an effective beam-width of about 1.5 arc sec, the limit set by signal-to-noise ratio<sup>5</sup>. Examples of data restored by this method are plotted in Figs. 1*c* and *d*.

The five occultations yielded ten scans across the source, from which the radio-brightness contours shown in Fig. 2 were determined by the following procedure. The peaks of each restored scan were assumed to coincide with the centres of the components of the source. Points corresponding to 0.8, 0.6, 0.4 and 0.2 of the peak intensity of component *B* were then marked off along the appropriate position angle. Lines were drawn through these points

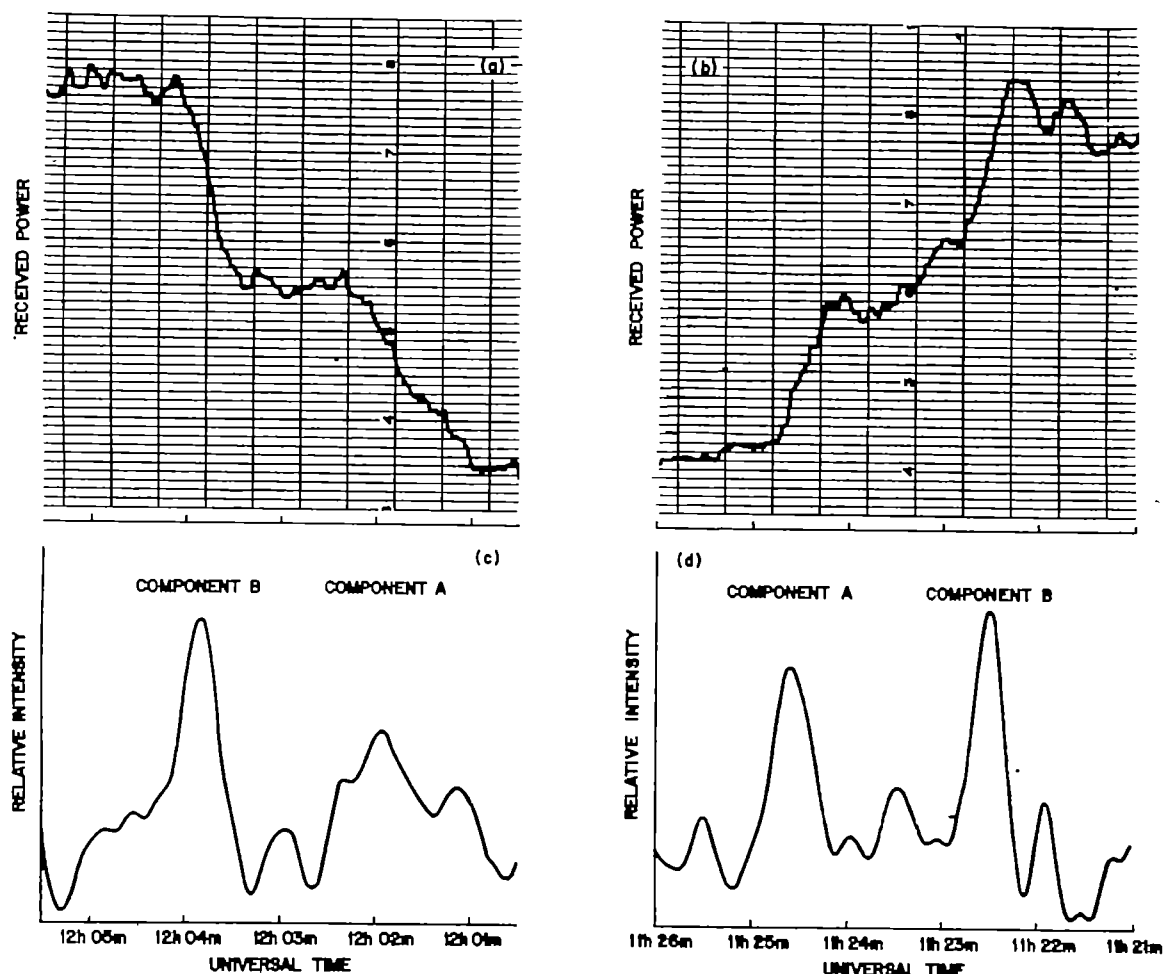

Fig. 1. Lunar occultation of December 9, 1963. Analogue records with receiver time constant of 14 sec: (a) emission; (b) immersion. Brightness distributions restored with an effective beam-width of 2.4 arc sec: (c) emission; (d) immersion.

Fig. 2. Brightness contours of 30273 determined from occultation observations restored with an effective beam-width of 1.5 arc sec. Numbers on the contours indicate intensity on a scale of 10 relative to the central maximum of component B. The straight, dashed line indicates the extent of the optical jet. Arrows show the directions in which the Moon's limb crossed the components.

perpendicular to the direction of the occultation. A first approximation to the contours was obtained by inscribing smooth curves inside the envelopes determined by the lines. The contour map thus formed was divided into strips 1.5 arc sec wide perpendicular to the position angle of a given occultation. By integrating along these strips a scan across the source was simulated. The observed and simulated scans were compared and the locations of the contours adjusted to minimize their differences. This procedure was repeated for several position angles. The dashed contour delineates the region beyond which there was no detectable signal.

Component A is narrow and elongated along the axis of the components. At right angles to this axis it remains unresolved with the present resolution of 1.5 arc sec. Component B also shows elongation along the line joining the components. By contrast, observations at 410 Mc/s suggest that component B may be elongated perpendicular to the axis<sup>1</sup>. The limitations inherent in strip scans must be borne in mind when one examines the contour diagram. In particular, the increased separation between contours of component B near position angle 150° could in part be attributed to confusion with the extended region of component A.

The record of Fig. 1a is of particular interest because the Moon's limb receded along position angle 239°, which is only 15° from the line joining the centres of the components. The extension of component A can be seen quite clearly on the record as a relatively slow rise with no

associated diffraction pattern. The plateau between 12h 02.4m and 12h 03.5m U.T. indicates that component A ends approximately 10 arc sec from the centre of component B. This feature of the radio emission shows remarkable correspondence with the optical data<sup>2</sup>.

The centre positions of the two components have been calculated from the universal times corresponding to the peaks on the restored scans. The mean right ascensions and declinations (Epoch 1950) together with the root mean square errors are:

Component A: 12h 26m 32.42s ± 0.04s + 02° 19' 29".2 ± 0".4.  
Component B: 12h 26m 33.27s ± 0.04s + 02° 19' 43".7 ± 0".8.

The radio position for component B is 1.5 arc sec north-west of the corresponding optical position<sup>3</sup>. If we ascribe this difference to systematic causes and assume that the stellar object lies at the centre of component B, then the position of the optical jet is that indicated in the contour diagram by the straight, dashed line.

The ratio of the flux of component A to that of component B is 1.00 : 0.92. The combined flux of the two components at 950 Mc/s is  $4.5 \times 10^{-26}$  M.K.S. units (assuming  $M_{87} = 290 \times 10^{-26}$  units). Hence, the flux of component A at this frequency is  $2.7 \times 10^{-26}$  units and that of component B is  $2.1 \times 10^{-26}$  units. These

values are in accord with fluxes predicted from previous observations<sup>1,4,5</sup>.

I thank Dr. S. von Hoerner of the National Radio Astronomy Observatory for supplying his Fortran computer programme and Dr. W. Nicholson of H.M. Nautical Almanac Office for predicting the occultations and calculating the source positions. Mr. J. Ball assisted with the computations.

## ASTRONOMY

### Correlation between the Twelve High-velocity Neutral Hydrogen Clouds and a Feature of the Sky in the Radio Continuum

Hulsbosch and Raimond<sup>1</sup> have discovered a region, 100° in diameter, which contains twelve clouds of neutral hydrogen distinguishable from the general background emission by their exceptionally high Doppler shifts. These shifts correspond to velocities from -85 km/sec to -175 km/sec relative to the Sun. It is interesting that there appears to be a relationship between these peculiar neutral hydrogen clouds and the features of the radio continuum emission from the high galactic latitudes.

Table 1. POSITION ANGLES OF OCCULTATIONS

Date of occultation	Position angles			
	Component A		Component B	
	Immersion	Emergence	Immersion	Emergence
Dec. 9, 1963	186°	239°	183°	241°
April 24, 1964	110°	325°	109°	325°
July 14-15, 1964	182°	305°	181°	304°
Sept. 7, 1964	154°	303°	183°	304°
Nov. 23, 1964	104°	332°	108°	334°

The existence of the zinc blende structure at these three points in the triangle leads us to expect adamantine solid solution at all compositions inside the triangle. The ease with which equilibrium can be attained will, it is to be hoped, stimulate work on the many similar systems that can be postulated from known adamantine compounds.

## GEOFYSICS

### Airborne Observations of Natural Radioactivity in the Atmosphere

MANY observations of natural radioactivity in the atmosphere have been made<sup>1</sup>, especially at ground-level. Radon and its decay products predominate<sup>2</sup>.

This communication describes some measurements with a scintillation detector of background counting rates at altitudes up to 3.6 km. The day-to-day variations in counting rate were surprisingly large, and were found to occur mainly in the atmosphere between the ground and temperature inversion layers. The variations are due principally to changes in concentration of natural radioactivity in the atmosphere.

Fig. 1. Counting rate versus altitude

The detector, a scintillation unit with a cylindrical sodium iodide crystal of diameter 10 cm and height 7.5 cm, was mounted behind the tailplane of a DO 3 aircraft and could detect  $\gamma$ -rays coming from all directions. The flights were made near Gatton (elevation 100 m), Queensland, 85 km inland from the eastern coast of Australia. The airstreams were essentially from the east (maritime) for the four days immediately before the day of the first flight (June 5). Wind directions changed on June 6, and, for the subsequent days on which flights were made, the airstreams were essentially from the west (continental).

Counting rates were measured at intervals of 150 m altitude and the values obtained for the six flights are plotted against altitude (Fig. 1). The altitudes of temperature inversion are noted. The counting rates observed on June 5, in the maritime airstream, were the lowest of the series, and varied smoothly with altitude. The initial decrease in counting rate with altitude was due to

absorption by air of  $\gamma$ -rays from radioisotopes in the ground<sup>3</sup>. At higher altitudes the counting rate increases with altitude due to cosmic rays<sup>4</sup>. Counting rates, especially at heights less than 2 km, were higher on days of continental airstream (June 7-12) and varied more abruptly with altitude. The main increases in counting rates, as compared with results on June 5, occurred below the temperature inversion layers. This indicates that the increases were due to radioactivity in the atmosphere, and that it probably originated from the ground.

Simultaneous measurements of counting rate and relative humidity were made at 1-min intervals during several flights at constant altitude. During one flight the aircraft passed through successive moist and dry air regions at about 2-min intervals, and higher counting rates were recorded in the moist air than in the dry. These observations were made in clear air about 10-15 min before cloud formation was observed. The moist air pockets, which were not found an hour earlier at this altitude, may have been carried up by convection, thereby containing more natural radioactivity than the surrounding air.

It was probably mainly radon and its decay products which were detected. The principal  $\gamma$ -rays originate from lead-214 and bismuth-214 (ref. 5). The scintillation detector 'sees'  $\gamma$ -rays emitted by these isotopes distributed in the sphere of radius approximately 300 m about the aircraft. It has been estimated that the present detector will record 8 c.p.s. as a result of a uniform concentration of  $10^{-17}$  curies/c.c. of both lead-214 and bismuth-214 in the atmosphere at an altitude of about 2 km. The calculation<sup>6</sup>, allowing for the build-up of  $\gamma$ -ray quanta in air, gives a counting rate about eight times that for calculations based on exponential absorption of  $\gamma$ -rays. The

maximum increase in counting rate above the results of June 5 was about 46 c.p.s., that is, a concentration of about  $6 \times 10^{-17}$  curies/c.c. This is well within the range of concentrations found by other investigators<sup>7</sup>.

These observations show that by using a scintillation detector mounted on an aircraft, instantaneous measurements can be made of the natural radioactivity in the atmosphere. An air mass may be identified as being of essentially continental origin when the concentration of natural radioactivity is high. Estimation of the efficiency of scouring of radioactive aerosols by rain, and the degree of mixing across a stable interface between two fluids such as at the top of stratocumulus cloud, are two problems which may merit investigation with this technique.

### Possible Destruction of Ozone by Volcanic Material at 50 mbar

VERTICAL ozone distributions over Boulder, Colorado ( $40^\circ$  N.), showed a persistent dip in the ozone concentration at 50 mb over the period from March 9 to April 10, 1964. At the middle of the period the dip reached a maximum amplitude of about 50 micro-mbar less than the neighbouring ozone partial pressures, and a 'half-width' of about 5 to 10 mb. The rise in ozone concentration below the 50-mb level was appreciably steeper than the lines of equal mixing ratio, even in the mean of all 23 soundings taken during the above period.

Fig. 1 shows the mean plot of partial pressure of ozone against total pressure for the nine consecutive soundings from March 16 to 27, 1964, over Boulder.

These observations appear to require an 'ozone sink' at 50 mb at the time and place of observation. It is tentatively suggested that such a sink could have been present in the form of a concentrated layer of volcanic dust. Meinel and Meinel<sup>1,2</sup> reported such dust, attributed to the eruption of Mt. Agung on Bali on March 17, 1963, as late as November 1963. Similar observations have been reported from India, Australia and South Africa.

Mossop<sup>3</sup> gives estimates of mean concentration and diameter of samples collected over Australia, while Bigg (personal communication) has furnished photographs showing patches of volcanic dust as far south as  $41^\circ$  S. and having a vertical thickness of the order of one kilometre or less.

From the persistence of the 'ozone hole' over Boulder and the winds then prevailing at the 50-mb level, which were very light, it is estimated that the patch of dust must have extended over horizontal distances of the order of a few thousand kilometres. Confirmation from stations in the United States Air Force ozone-sonde network gives support to this picture. A similar 'ozone hole' was found in soundings from Fort Collins, Colorado, on March 18 and March 25; from Albuquerque, New Mexico, on March 18 and April 8; and from Bedford, Massachusetts, on April 1 and April 2.

A model of such a dust layer has been drawn up and the resulting ozone profile computed. This model requires a thin layer having a vertical mixing coefficient more than an order of magnitude less than current estimates of the mean value. On the model chosen a destruction rate of one ozone molecule in every  $3.5 \times 10^7$  per sec is required to give rise to the observed ozone profile. As the mass of ozone per unit volume at 50 mb is several orders of magnitude greater than the estimated mass of dust per unit volume, such destruction must be catalytic in nature, most likely due to the adsorption of ozone molecules on the surface of the dust particles with subsequent decomposition on collision with a second ozone molecule.

Fig. 1. Mean of nine consecutive ozone soundings, March 16-17, 1964

In conclusion, it is emphasized that this model is put forward to explain a very particular event and does not necessarily imply that dust is normally present in sufficient concentration to appreciably affect the ozone distribution at these levels. Nevertheless, the implications regarding circulation and vertical eddy diffusion require further investigation, as does the possibility that a concentration mechanism operated to produce the high dust concentrations required here (and observed over Australia).

I thank my colleagues at the National Center for Atmospheric Research, members of the U.S. Air Force ozone-sonde network, and Dr. E. K. Bigg for their assistance in this work.

## METALLURGY

### Effects of Silver and Two-step Ageing Treatments on a Weldable Alloy of Aluminium, Zinc and Magnesium

POLMEAR and co-workers<sup>1-3</sup> have shown that small additions of silver to Al-Zn-Mg alloys can bring about increases in strength, and, by retarding over-ageing, allow alloys to be aged at higher temperatures. When silver was added to 'DTD 683' (ref. 3) the increase in hardness at ageing temperatures up to  $135^\circ$  C was small, the main advantage being that high hardness levels were maintained when ageing at temperatures up to  $180^\circ$  C.

Taylor<sup>4</sup> has shown that to produce the highest mechanical properties in a reasonably short time in weldable Al-Zn-Mg alloys a 2-step ageing treatment is required. The alloy is first aged at a temperature below  $100^\circ$  C, and then aged at or above  $120^\circ$  C, when reversion is followed by rapid ageing to give higher strengths than could be obtained by ageing directly at the higher ageing temperature. Taylor's work does not show whether the use of 2-step ageing treatments allows high hardness levels to be maintained at temperatures much more than  $135^\circ$  C. The use of high ageing temperatures could be an advantage in weldable Al-Zn-Mg alloys, since the heat-affected zone should be narrower the higher the ageing temperature.

Experiments to evaluate the effect of silver and the effect of 2-step ageing treatments on commercially produced weldable Al-Zn-Mg alloys have been carried out on two alloys containing nominally 5.0 per cent (weight) Zn, 1.3 per cent Mg, 0.1 per cent Cr, and 0.2 per cent Mn, one of which contained an addition of 0.45 per cent Ag. In the first instance hardness has been used as a measure of strength, though it is recognized that hardness is not a fundamental property.

Specimens of both alloys were solution-treated at  $460^\circ$  C for 30 min and water quenched. For each alloy specimens were first aged for 7 days at  $20^\circ$  C, 7 days at  $70^\circ$  C and 7 days at  $100^\circ$  C, before being aged at  $120^\circ$  C,  $140^\circ$  C,  $160^\circ$  C and  $180^\circ$  C. In addition some specimens were aged directly at the final ageing temperatures without a preliminary low-temperature age. The initial low-temperature ageing treatments were chosen arbitrarily.

In the silver-free alloy, 2-step ageing treatments resulted in higher peak hardness values at all ageing temperatures between  $120^\circ$  and  $180^\circ$  C, the effect being more marked the higher the final ageing temperature. The best results were obtained when the first ageing was for 7 days at  $70^\circ$  C.

Fig. 1. Peak hardness against final ageing temperature for (1) 5.0 per cent Zn, 1.8 per cent Mg alloy aged directly at the final ageing temperature; (2) The same alloy first aged for 7 days at 70° C; (3) 5.0 per cent Zn, 1.8 per cent Mg, 0.45 per cent Ag alloy aged directly at the final ageing temperature

In the silver-containing alloy the peak hardness obtained at the final ageing temperature was effectively the same, whether the specimens were given a preliminary period of ageing at low temperature or not.

The effect of the silver addition on the silver-free alloy was similar to the effect of preliminary ageing at low temperature, in that both increased the peak hardness at the final ageing temperature, and both had the greatest effect when the final ageing temperature was high. These results are summarized in Fig. 1, where peak hardness is plotted against the final ageing temperature (1) for the alloy of 5.0 per cent Zn and 1.8 per cent Mg, aged directly at 120°–180° C; (2) for the same alloy first aged for 7 days at 70° C; (3) for the alloy of 5.0 per cent Zn, 1.8 per cent Mg and 0.45 per cent Ag, aged directly at 120°–180° C.

The results show that for the composition investigated, an addition of silver brings about a small increase in strength when ageing at 120° C, but is a distinct advantage in allowing the use of higher ageing temperatures. However, the same advantage can be obtained by using a two-step ageing treatment.

### Influence of Zirconium Additions on the Epsilon Phase of the Titanium-Aluminium System

THE TiAl phase ( $\epsilon$ ) of the aluminium-titanium system exists as a single-phase field and can be achieved as a high-temperature phase without a polymorphic phase transformation. Results of an early investigation by the Armour Research Foundation indicated that an alloy of 36 per cent aluminium with 64 per cent titanium had superior oxidation resistance at 1,500° F, good hot hardness, and low density; however, it lacked any degree of room-temperature or elevated-temperature ductility<sup>1</sup>. The cause of this brittleness appeared to be the ordered face-centred tetra-

gonal lattice structure, in which [002] planes of aluminium atoms were alternated with titanium atoms. It was assumed that if the  $c/a$  ratio could be reduced to unity, and the atomic arrangement could be disordered, the ductility of the  $\epsilon$  phase could be improved. Keesler and McAndrews<sup>2</sup> tried to reduce the  $c/a$  ratio to unity by the additions of 13 different elements. Davies<sup>3</sup> in 1959 suggested the addition of Zr as a means of reducing the  $c/a$  ratio. Sandlin and Klug<sup>4</sup> and Troup<sup>5</sup> continued to study the effect of Zr additions to the TiAl binary. The purpose of our investigation was to refine the 2,325° F  $\epsilon$ -phase boundary of the Al-Ti-Zr system outlined by the earlier investigators and to determine the influence of zirconium on the  $c/a$  ratio within the  $\epsilon$  phase at this temperature.

Eighteen experimental alloys were prepared from high-purity aluminium (99.99 per cent), titanium (99.99 per cent), and zirconium (99.72 per cent Zr containing 0.21 per cent Hf). Twenty-gram button specimens of each composition, as indicated in Fig. 1, were arc-melted in a high-purity argon-helium atmosphere. Each button was melted six times and inverted between each melt to ensure homogeneity. Weight losses during melting did not exceed 0.69 per cent. Nominal and analysed compositions agreed within 1 per cent. The specimens were wrapped in tantalum foil, encapsulated in quartz, and homogenized at 2,325° F for 24 h. After heat treatment, the quartz capsules were quenched in brine to preserve the high-temperature phase/s present.

Filings for X-ray analysis were passed through a 325-mesh screen. This powder was wrapped in tantalum foil and subjected to a low-temperature anneal in evacuated 'Vycor' tubes containing spectroscopically pure argon at a pressure of less than one micron. The latter operation was necessary to remove the effects of cold work.

Powder studies were conducted using a Siemens 114.6 mm camera with Straumanis mounting. Copper K $\alpha$  radiation was filtered with nickel. The  $d$ -values taken from the film, corrected for shrinkage, were compared with the  $d$ -values of TiAl, TiAl<sub>3</sub>, Ti<sub>3</sub>Al, Al-Zr phases, and possible contaminants. Specimens 1, 2, 3, 5, and 7 were in a two-phase region of TiAl and Ti<sub>3</sub>Al. Specimens 15, 16, 17 and 18 were in a two-phase region of TiAl and TiAl<sub>3</sub>. Specimens 4, 6, 8, 9, 10, 11, 12, 13, and 14 were within the boundary of the TiAl phase. The maximum intensity  $d$ -values of the contaminants Ti<sub>3</sub>O<sub>5</sub> and Al<sub>2</sub>O<sub>3</sub> were identified in some films. Fig. 1 presents the TiAl phase boundary determined during this study as compared with the investigation by Troup.

The quenched specimens were also examined metallographically to determine their metallurgical structure.

Fig. 1. Nominal compositions and TiAl phase boundary at 2,325° F; —, present work; ---, after Troup; solid circles represent compositions investigated

Two etching procedures were used to obtain photomicrographs of homogenized titanium-rich samples: (1) Kroll's etch (6 ml.  $\text{HNO}_3$ , 3 ml.  $\text{HF}$ , 91 ml.  $\text{H}_2\text{O}$ ) with 10-sec immersions, and (2) electrolytic etch (60 ml.  $\text{HClO}_4$ , 350 ml.  $\text{C}_2\text{H}_5\text{OC}_2\text{H}_4\text{OH}$ , 360 ml.  $\text{CH}_3\text{OH}$ ) using a stainless steel cathode for various times at 20 V and a current density of 780 m.amp/cm<sup>2</sup>. Aluminium-rich samples were etched with an etchant commonly used for aluminium (45 ml.  $\text{H}_2\text{O}$ , 9 ml.  $\text{HNO}_3$ , 9 ml.  $\text{HF}$ , 30 ml.  $\text{H}_3\text{PO}_4$ , 6 ml.  $\text{HC}_2\text{H}_3\text{O}_2$ , 5-10 ml.  $\text{H}_2\text{O}_2$ ) by immersion for 3-6 min. The metallographic data supported the results of the X-ray examination.

The  $c/a$  ratios of specimens in the TiAl single phase region were computed by the Myers and Davies<sup>4</sup> graphical method of precise lattice-parameter determination. The 20 values within the 60°-160° range were used for these computations. The binary limits of the TiAl phase were found to be from about 51.5 to 63.5 atomic per cent aluminium.

The average  $c/a$  ratio for the intermediate phase TiAl was computed to be 1.019. The  $c/a$  ratio was found to increase slightly as the zirconium substitutionally replaced the titanium within the TiAl lattice. The  $c/a$  ratio at the maximum solubility limit of zirconium within the single phase was 1.026. The  $c/a$  ratio did not approach unity with Zr additions as had been previously reported but actually was found to increase.

## CHEMISTRY

### The System Dicalcium Silicate-Merwinite

It was reported earlier<sup>1</sup> that a new compound of the approximate molar composition  $(2\text{CaO} \cdot \text{SiO}_2)_{1.4}(\text{3CaO} \cdot \text{MgO} \cdot 2\text{SiO}_2)_{0.6}$  had been located in the system  $2\text{CaO} \cdot \text{SiO}_2 - 3\text{CaO} \cdot \text{MgO} \cdot 2\text{SiO}_2$ . This system, relevant to processes in the iron, slag and slag cement industries, has now been fully explored and the stable phase assemblages between the new compound and adjoining compounds have been established. The results are presented in the phase diagram given in Fig. 1.

The compositions studied were prepared from crushed quartz (99.95 per cent pure),  $\text{CaCO}_3$  (99.9 per cent pure) and  $\text{MgO}$  (99.9 per cent pure) by ignition at 1,250° C in platinum boats in a platinum/rhodium resistance furnace. The fineness of the reaction mixture is of importance to the formation of the new compound, and during a heat treatment of 10 days duration the mixtures were ground frequently to pass a 300 mesh sieve.

The liquidus, covering the temperature range 1,800° C-2,130° C, was established by means of special techniques of high-temperature microscopy<sup>1</sup> which showed dicalcium silicate to be the primary phase throughout the system.

Fig. 1 The system  $2\text{CaO} \cdot \text{SiO}_2 - 3\text{CaO} \cdot \text{MgO} \cdot 2\text{SiO}_2$ . ●, Liquidus temperature; ○, points at which determinations were made with the high-temperature X-ray camera; T, new calcium magnesiosilicate; ss, solid solution; ⊕, temperature of  $\alpha \rightarrow \alpha'$  transition of  $2\text{CaO} \cdot \text{SiO}_2$  by optical determination; —, phase boundary; C,  $\text{CaO}$ , S,  $\text{SiO}_2$ ; L, liquid; M,  $\text{MgO}$ .

First liquid is formed throughout the system at 1,575° C, where merwinite decomposes to give  $\alpha 2\text{CaO} \cdot \text{SiO}_2$ , periclase ( $\text{MgO}$ ) and liquid. At 1,590° C,  $\text{MgO}$  dissolves leaving dicalcium silicate and liquid. The presence of periclase in the system within this narrow range of temperature was established by X-ray analysis of quenched products. These findings are compatible with the accepted view<sup>2</sup> of the melting behaviour of pure merwinite, and of the position of the invariant point<sup>3</sup> in the system  $\text{CaO}-\text{MgO}-\text{SiO}_2$  at which  $2\text{CaO} \cdot \text{SiO}_2$ , periclase and merwinite co-exist with liquid.

In the region in which periclase is present, the system  $2\text{CaO} \cdot \text{SiO}_2 - 3\text{CaO} \cdot \text{MgO} \cdot 2\text{SiO}_2$  ceases to be binary.

The subsolidus regions in which the system is binary were explored systematically, by means of high-temperature X-ray analysis<sup>1</sup> at ascending temperatures of preparations first annealed at 500° C.

The new calcium magnesiosilicate decomposes into  $\alpha 2\text{CaO} \cdot \text{SiO}_2$  and merwinite at 1,460° C. It was detected in the system over the wide range of compositions between 5 and 95 per cent of merwinite.

Magnesium ions enter into solid solution in the structures of the  $\gamma$ - and  $\alpha'$ -polymorphs of dicalcium silicate whereas the  $\alpha$ -polymorph does not appear to form a solid solution. The  $\beta$ -polymorph of dicalcium silicate does not form a part of the stable assemblages. The solubility of Mg ions in the  $\gamma$ -structure increases with temperature and reaches a maximum equivalent to approximately 9 per cent (weight per cent) merwinite at 830° C. The temperature of the inversion  $\gamma 2\text{CaO} \cdot \text{SiO}_2 \rightarrow \alpha' 2\text{CaO} \cdot \text{SiO}_2$  is raised from 830° for pure  $2\text{CaO} \cdot \text{SiO}_2$  to 990° C for the maximum  $\gamma 2\text{CaO} \cdot \text{SiO}_2$  solid solution. The temperature of the  $\alpha 2\text{CaO} \cdot \text{SiO}_2 \rightarrow \alpha' 2\text{CaO} \cdot \text{SiO}_2$  inversion is lowered to 1,360° C as the proportion of merwinite increases. The composition of the maximum solid solution of Mg ions with  $\alpha' 2\text{CaO} \cdot \text{SiO}_2$  occurs at 82.5 per cent  $2\text{CaO} \cdot \text{SiO}_2$ , 17.5 per cent  $3\text{CaO} \cdot \text{MgO} \cdot 2\text{SiO}_2$ . The  $\alpha \rightarrow \alpha'$  inversion is accompanied by changes in birefringence observable by high-temperature microscopy and the locus of the  $\alpha \rightarrow \alpha'$  inversion was determined by this method as well as by X-ray analysis. The new calcium magnesiosilicate

co-exists with the polymorphs of  $2\text{CaO} \cdot \text{SiO}_2$  and with merwinite, and throughout the system its X-ray diffraction pattern (already published<sup>1</sup>) remains unaltered in terms of reflexions present and their relative intensities. This is consistent with the view that it is a singular compound.

### Electronic Spectrum of $\text{IO}^-$ in Solution

Compounds of iodine in the +1 oxidation state are unstable in aqueous solution, and for this reason their chemistry is still not clearly defined. Recording the absorption spectrum of  $\text{IO}^-$  should be helpful for a systematic investigation of this group. Conflicting reports have been published on this subject<sup>1,2</sup>. Apart from the instability of  $\text{IO}^-$ , the main difficulty arises from the overlap of its spectrum with that of other iodine compounds, in particular that of  $\text{I}_2^-$ . High alkalinity and low  $\text{I}^-$  concentration are desirable for suppressing the formation of  $\text{I}_2^-$  and other +1 iodine compounds as  $\text{HIO}$ ,  $\text{I}_2\text{OH}^-$ ,  $\text{I}_2\text{O}$  (ref. 1). Here we report the results of a spectrophotometric examination of iodine in highly concentrated alkali solutions.

Solutions of iodine in 4 N sodium hydroxide were prepared by rapidly adding 10 ml. of 4 N sodium hydroxide solution to weighed quantities of iodine in 'low actinic' flasks. The sodium hydroxide solution was previously kept at 25° C, its delivery time was relatively short and the flask was shaken to ensure the fast dissolution of iodine in the alkali. Some solution was then rapidly transferred to a 1-cm silica cell situated in the thermostated cell compartment (25° C) of a Hilger 'Uvispek' spectrophotometer. The absorbance was measured against a reference solution of 4 N sodium hydroxide. Care was taken not to expose the cell to light apart from the short periods required for the spectrophotometric measurements. This was done because the solutions appeared to be sensitive to light. Measuring the absorbance ( $A$ ) at a fixed wave-length  $\lambda$ ,  $A$  was found to decrease with time.

Fig. 1. Kinetic curves for the disproportionation of  $\text{IO}^-$  in 4 N sodium hydroxide. Curves 1, 2 and 3, ( $\text{I}_2$ ) =  $4.25 \times 10^{-4}$  M,  $\lambda$  = 290, 295 and 320 m $\mu$  respectively. Curve 4, ( $\text{I}_2$ ) =  $3.23 \times 10^{-4}$  M,  $\lambda$  = 300 m $\mu$ . Curves 5 and 6, ( $\text{I}_2$ ) =  $3.84 \times 10^{-4}$  M,  $\lambda$  = 280 and 260 m $\mu$ , respectively. Curve 7, ( $\text{I}_2$ ) =  $4.3 \times 10^{-4}$  M,  $\lambda$  = 248 m $\mu$  (before measuring  $A$  each sample was diluted with 4 N sodium hydroxide by a factor of 1/100).

Fig. 2. The electronic spectrum of  $\text{IO}^-$  in solution

Fig. 1 shows plots of  $1/A$  against time at few wave-lengths, where  $\text{I}^-$  and  $\text{IO}_3^-$  scarcely absorb (curves 1-6). The light-absorbing species obviously decays by a second-order reaction. We identify this species with  $\text{IO}^-$ , which is produced by the relatively fast reaction:

and which undergoes the overall reaction:

The analogous reactions for  $\text{ClO}^-$  and  $\text{BrO}^-$  are also of second order<sup>3,4</sup>. The rate-determining step for the decomposition of the hypohalites is presumably:

From the relation  $A = \epsilon_{\text{IO}^-}(\text{IO}^-) + \epsilon_{\text{I}^-}(\text{I}^-) + \epsilon_{\text{IO}_3^-}(\text{IO}_3^-)$  and the stoichiometry of reactions (1) and (2) we derive:

$$[A - a(5/3 \epsilon_{\text{I}^-} + 1/3 \epsilon_{\text{IO}_3^-})]^{-1} = \frac{k}{\Delta \epsilon} t + \frac{1}{\Delta \epsilon a} \quad (4)$$

where  $a$  is the initial concentration of iodine,  $k$  is the apparent rate constant and  $\Delta \epsilon = \epsilon_{\text{IO}^-} - 2/3 \epsilon_{\text{I}^-} - 1/3 \epsilon_{\text{IO}_3^-}$ .  $\epsilon_{\text{I}^-}$  and  $\epsilon_{\text{IO}_3^-}$  were determined by measuring the spectra of  $\text{I}^-$  and  $\text{IO}_3^-$  in 4 N sodium hydroxide solution (in the spectral region examined the correction for  $\text{IO}_3^-$  could be ignored). To test the validity of equation (4) and determine  $\epsilon_{\text{IO}^-}$  in the region where  $\text{IO}^-$  and  $\text{I}^-$  strongly absorb, samples of  $\text{IO}^-$  solution were withdrawn at appropriate times from the thermostatic flask and rapidly diluted with 4 N sodium hydroxide by a factor of 100. The solutions thus obtained were relatively stable and their spectra were measured. Curve 7 (Fig. 1) exemplifies the validity of equation (4). From the intercepts and slopes of the lines the rate constant  $k$  and  $\epsilon_{\text{IO}^-}$  could be determined.  $k$  appears to be constant, irrespective of  $\lambda$ , at  $(4.0 \pm 0.4) \times 10^{-3} \text{ M}^{-1} \text{ sec}^{-1}$ . Fig. 2 shows the absorption spectrum of  $\text{IO}^-$ . Raising the concentration of  $\text{OH}^-$  to 10 N had scarcely any effect on the spectrum, but  $k$  decreased to some extent: its value was  $(2.7 \pm 0.2) \times 10^{-3} \text{ M}^{-1} \text{ sec}^{-1}$  at 6 N sodium hydroxide and remained nearly the same at 10 N. This may be due to the presence of little  $\text{HIO}$  in the 4 N sodium hydroxide solution. On the other hand, at  $(\text{OH}^-) = 2 \text{ N}$  the spectrum was considerably changed, probably due to the formation of other iodine compounds.

The weak absorption band of  $\text{IO}^-$  has already been reported but with somewhat different shape and intensity ( $\epsilon_{\text{max}} = 60$ ) (ref. 1). This is probably due to the relatively low  $\text{OH}^-$  concentration used in that work (1 N). More-

over, no kinetic investigation was carried out and the extrapolation to zero time was performed graphically on the  $A-t$  curves. The spectrum at  $\lambda < 280$  m $\mu$  was not recorded earlier. It displays two absorption bands, one appearing as a shoulder at about 255 m $\mu$  and the other is of high intensity with  $\lambda_{\text{max}} < 235$  m $\mu$ .

The low-intensity bands of ClO $^-$ , BrO $^-$  and IO $^-$  appear at 290 $^{\circ}$ , 331 $^{\circ}$  and 365 m $\mu$ , respectively, with  $\epsilon_{\text{max}}$ : 360, 326 and 81 M $^{-1}$  cm $^{-1}$ , respectively. The valency shell of the hypohalite ions is isoelectronic with that of the halogen molecules: (s $\sigma$ ) $^2$  (y $\sigma$ ) $^2$  (z $\sigma$ ) $^2$  (w $\pi$ ) $^4$  (v $\pi$ ) $^4$ , in the molecular orbital treatment. The low-energy band is probably due to the excitation  $^3J_g^+ \leftarrow ^1\Sigma^+$  which involves the transfer of the antibonding v $\pi$  electron to the more strongly antibonding w $\sigma$  orbital. As in the case of the halogen molecules this excitation is likely to bring about the dissociation of the hypohalite ions. The dissociation energy in the ground state  $D^{\circ}(\text{XO}^-)$  can be estimated from that of the XO radical, since XO $^-$  differs from XO by having one more antibonding v $\pi$  electron. This reduces the bond order from 3/2 to 1, that is,  $D^{\circ}(\text{XO}^-) \sim 2/3 D^{\circ}(\text{XO})$ . The estimated values for ClO $^-$ , BrO $^-$  and IO $^-$  are thus: 42, 37 and 28 kcal, respectively. The ground state probably correlates with O( $^3P_{2/2}$ ) and X( $^3P_{3/2}$ ), whereas the  $^1\Pi$  excited state may decompose to yield O( $^3P_2$ ) and X( $^1S_0$ ). If this is correct, then the corresponding potential curves should cross, since the electron affinity  $E(\text{O})$  is smaller than  $E(\text{X})$ . High kinetic energies are thus imparted to the dissociation products formed by irradiating the hypohalite ions in their low intensity bands. This may explain their high photochemical sensitivity\*. The subsequent reaction is probably:  $\text{O} + \text{XO}^- \rightarrow \text{XO}_2^-$ .

### An Effect of Ultrasonic Standing Waves on Electrodeposition

In the course of an investigation carried out here into the possibility of producing fine line patterns by using ultrasonic standing waves to control physical or chemical processes, the following electrochemical effect was observed.

Ultrasonic standing waves were set up in the electrolyte of a small plating cell, using a barium titanate disk transducer and, 2.5 cm from it, a glass block as a reflector. In the gap between the reflector and transducer was a sheet nickel cathode, 1.5 cm  $\times$  1 cm, arranged so that the standing waves were perpendicular to its surface. Parallel to the cathode and about 5 cm from it was a copper anode 2.5 cm $^2$ . When small amounts of copper were plated on the cathode by passing about 8 m.amp through the cell, it was found that the deposit was formed in regular lines corresponding to the standing waves in the electrolyte. Heavier deposition caused the pattern to disappear. The best electrolyte found was 1 g/l. copper sulphate pentahydrate; the addition of complexing agents had no observable effect. Patterning was found at 2, 6 and 10 Mc/s, giving 27, 80 and 134 lines/cm, but becoming very faint at the highest frequency.

No reference has yet been found to this effect in the literature, but it may be related to the Debye potentials observed by Yeager *et al.*<sup>1</sup>. These workers found and measured the variation in the potential of a small platinum

electrode as it was moved through standing waves at 265 kc/s in various electrolytes. This was in the region of 10  $\mu$ V.

Unsuccessful attempts have been made to measure the difference in current passed by two wire cathodes spaced a quarter of a wave-length apart on the standing wave field; but in view of the very small voltages found by Yeager *et al.*, it is to be expected that more sensitive experimental techniques would be needed than were available.

It is not known whether, at the ultrasonic power and frequencies used, the Debye voltage is sufficient to cause the variation in plating thickness observed, or whether some other mechanism is responsible.

This work is the subject of a provisional patent.

### Structural Differences between the Alkali Imidodisulphates

It has long been known from goniometric measurements<sup>1</sup> that there are morphological similarities between ammonium and potassium imidodisulphates (or iminodisulphonates), NH(SO $_3$ NH $_2$ ) $_2$  and NH(SO $_3$ K) $_2$ . The crystal structure of the potassium salt<sup>2</sup>, which has recently been refined<sup>3</sup>, conforms accurately to the space-group C 2/c. Preliminary X-ray examination of single crystals at room temperature revealed<sup>4</sup> that ammonium imidodisulphate differs somewhat in structure from the potassium salt in that its true unit cell has a *b*-axis three times as long ( $3 \times 7.74 = 23.2$  Å) as a pseudo-cell isomorphous with the potassium salt. Rubidium imidodisulphate appears to have a five-fold superlattice since, on *b*-axis photographs, a few reflexions can be seen on up to four additional weak layer-lines between adjacent strong layer-lines. In both salts, reflexions on the extra layer-lines are of very low intensity. We have investigated these structural irregularities by means of X-ray diffraction and broad-line nuclear-magnetic-resonance spectroscopy.

Negative piezo-electric tests<sup>5</sup> imply that at room temperature the structure of neither ammonium nor rubidium imidodisulphate departs significantly from centrosymmetry. From X-ray diffraction examination, the pseudocell [110] axis of ammonium imidodisulphate shows at 300° K a true repeat distance of  $3 \times 7.50 = 22.5$  Å; the  $(3n+1)$  and  $(3n+2)$ th layer-lines are always very weak (where  $n = 0, 1, 2, \dots$  is the layer-line number of the pseudocell). This is consistent with the triple-cell picture in which the true cell is C-face centred. At 80° K, the same axis exhibits only one weak layer-line between each pair of strong ones and the axial length is  $2 \times 7.49 = 15.0$  Å. This suggests that at low temperatures there is a transition from the triple unit cell, which exists at room temperature, to a cell having dimensions comparable with those of the potassium salt but in which true C-centring is replaced by pseudo C-centring.

From an approximate least squares X-ray refinement<sup>6</sup> of the ammonium imidodisulphate structure, carried out on the pseudocell reflexions only, and with the assumption of isomorphism with potassium imidodisulphate, it appears that the structure in the pseudocells is closely related to that of the potassium salt. Under similar conditions, the rubidium imidodisulphate structure did not refine satisfactorily. In this salt, the few exceedingly weak extra reflexions on *b*-axis X-ray photographs at room temperature are confined to the  $(5n \pm 1)$ th layer-lines ( $n = 0, 1, 2, \dots$ ), where the true axis length is  $5 \times 7.68 = 38.4$  Å; low-temperature photographs suggest that the quintupled cell persists down to 80° K. On room tempera-

ture rubidium salt rotation photographs about the  $5 \times 7.54 = 37.7 \text{ \AA}$  long [110] axis of the pseudo-cell, regarded as [510] of the true cell, a few extra reflexions were detected on the  $(5n+2)$  and  $(5n+3)$  layer-lines but none on the  $(5n+1)$  or  $(5n+4)$  layers. Neither at  $80^\circ$  nor at  $300^\circ \text{ K}$  were any such pronounced intensity differences apparent in ammonium imidodisulphate between one weak layer-line and another.

Attempts to prepare thallous imidodisulphate by double decomposition of the fairly soluble (41 g in 100 g water at  $20^\circ \text{ C}$ ) ammonium imidodisulphate were unsuccessful; possibly the Capetan<sup>8</sup> method, via the sulphamate, or a method analogous to that due to Baumgarten<sup>9</sup> for the preparation of ammonium and potassium imidodisulphates, would be better. Morphological evidence<sup>10</sup> indicates that the ammonium, potassium, and thallium salts of methionic acid,  $\text{CH}_3(\text{SO}_3\text{H})_2$ , which is iso-electronic with imidodisulphuric acid, are isomorphous with the imidodisulphates. While potassium methionate<sup>11</sup> is isostructural with potassium imidodisulphate, no superlattice structure analogous to that in ammonium imidodisulphate has been seen in ammonium methionate<sup>4</sup>.

Proton magnetic resonance spectra of powdered ammonium, potassium, and rubidium imidodisulphates were recorded at  $28.6 \text{ Mc/s}$  and with an  $H_1$  field of about 2 mG on a broad-line proton magnetic resonance apparatus<sup>12</sup> based on the Robinson<sup>13</sup> detector. Despite the small structural change revealed by X-rays, there was no significant change in the proton magnetic resonance line-width,  $\Delta H_{\text{m.s.l.}}$ , of  $4.8 \pm 0.5 \text{ G}$  when ammonium imidodisulphate was cooled from  $283^\circ$  to  $90^\circ \text{ K}$ . For the rubidium salt, there was no change between  $268$  and  $80^\circ \text{ K}$  in the line-width of  $2.6 \pm 0.5 \text{ G}$ . For potassium imidodisulphate, on the other hand, there was a possibly significant broadening in  $\Delta H_{\text{m.s.l.}}$  from  $2.3 \pm 0.5 \text{ G}$  at  $293^\circ$  to  $3.3 \pm 0.5 \text{ G}$  at  $80^\circ \text{ K}$ .

We thank Dr. W. G. Perdok for carrying out and communicating the piezo-electric measurements, Mr. R. Steadman for making X-ray equipment available, and Dr. M. R. Truter for help with low-temperature X-ray measurements.

### Reaction of Selenious Acid with Potassium Permanganate

ALTHOUGH the reaction of selenious acid with potassium permanganate has been used in estimating selenium<sup>1-3</sup> it has not been investigated in detail. According to Charlot<sup>4</sup> selenious acid reduces permanganate to manganese dioxide, which separates from the solution. But it is observed that when potassium permanganate is added to a large excess of selenious acid solution, the pink colour due to permanganate is discharged and the formation of precipitates of  $\text{MnO}_2$  does not take place. If selenious acid is not in large excess, only the precipitates of  $\text{MnO}_2$  appear shortly after the addition of permanganate. This

suggests that selenious acid first reduces permanganate ion to manganous ion which reacts with permanganate to form manganese dioxide. In the present investigation the reaction between selenious acid and potassium permanganate has been studied by physico-chemical methods.

The chemical analyses of the solution and the solid obtained by mixing solutions of selenious acid and potassium permanganate in different proportions reveal that, when selenious acid and permanganate are mixed in the molar ratio of 5:2, only a portion of selenious acid is oxidized to selenic acid. Complete oxidation of selenious acid occurs within 40 min if the molar ratio of  $\text{H}_2\text{SeO}_3$  to  $\text{KMnO}_4$  is equal to or less than 3:2. The net reaction between selenious acid and potassium permanganate in acidic medium may be represented as:

The reduction of permanganate by reaction (2) may be assumed to be negligible immediately after the addition of permanganate to selenious acid solution. Under such conditions the rate of oxidation of selenious acid is equal to  $5/2$  times the rate of reduction of permanganate which is directly related to the rate of disappearance of pink colour due to permanganate. The reduction of permanganate by selenious acid in the presence of sulphuric or phosphoric acid has been followed by measuring absorbance due to permanganate at different times (up to 90 sec) before the appearance of precipitate. The reaction (1) leading to the oxidation of selenious acid is found to be first order with respect to  $\text{H}_2\text{SeO}_3$ , first order with respect to permanganate, and zero order with respect to hydrogen ion. The rate law for the oxidation of selenious acid is given by the expression:

$$\frac{-d(\text{H}_2\text{SeO}_3)}{dt} = K(\text{H}_2\text{SeO}_3)(\text{MnO}_4^-)$$

The value of the rate constant  $K$ , calculated from the molar extinction coefficient of permanganate and optical density data taken with equimolar solutions of potassium permanganate and selenious acid (in  $0.6 \text{ N H}_2\text{SO}_4$ ) in the range  $(4.445 - 26.67 \times 10^{-4} \text{ N})$  is  $26.70 \pm 0.7 \text{ mol}^{-1} \text{ litre sec}^{-1}$  at  $26 \pm 0.2^\circ \text{ C}$ . The energy of activation evaluated from the values of  $K$  at different temperatures between  $20^\circ$  and  $32^\circ \text{ C}$ , is found to be  $20 \pm 0.5 \text{ kcal}$ .

Absorption measurements have been taken with the Spectronic '20' and the Beckman model 'D' spectrophotometer at  $520 \text{ m}\mu$  using a cell of  $1 \text{ cm}$  light path. We thank Dr. G. M. Naber and Dr. B. N. Ghosh, of the University of Bombay, for allowing us to use these instruments.

### Some Properties of Silicon Difluoride

GASEOUS silicon difluoride has been observed in spectral studies<sup>1</sup>, and polymers of composition  $(\text{SiF}_2)_n$  were prepared by Schmeisser<sup>2</sup> from magnesium and dibromodifluorasilane. However, a convenient preparation of both silicon difluoride gas and polymer was first described by

Pease<sup>3</sup> in 1958, in which silicon tetrafluoride was passed at low pressures over silicon at temperatures above 1,050° C. Pease showed that gaseous silicon difluoride would polymerize at low temperatures to form a rubbery polymer, and that it could be reacted with halogens or unsaturated organic molecules to give compounds containing SiF<sub>3</sub> groups.

We have extended these investigations and have found that both SiF<sub>2</sub> gas and its polymer (SiF<sub>2</sub>)<sub>n</sub> have some quite unusual properties.

In our experiments silicon tetrafluoride was passed over granular silicon at 1,150° C and the pressure after the hot zone was maintained at 0.1–1.0 mm by pumping. A mass spectrometric study showed that the gas emerging from the furnace contained only SiF<sub>2</sub> and SiF<sub>4</sub>.

Cooling the gas mixture to –196° C gave a red condensate which became a white rubbery solid at room temperature. We found that this polymer could be destructively distilled at 200°–350° C to give all the perfluorosilanes Si<sub>n</sub>F<sub>2n+2</sub> from SiF<sub>4</sub> through Si<sub>10</sub>F<sub>22</sub> (ref. 4). The compounds SiF<sub>4</sub>, Si<sub>2</sub>F<sub>6</sub>, Si<sub>3</sub>F<sub>8</sub>, and Si<sub>4</sub>F<sub>10</sub> have been isolated from the pyrolysis products, other compounds being identified by their mass spectra. Perfluorotrisilane and higher perfluorosilanes have not previously been described. They have similar boiling points to the corresponding silanes, but much higher melting points, for example, Si<sub>4</sub>F<sub>10</sub>, m. pt. 67° C, b. pt. 85° C; Si<sub>4</sub>H<sub>10</sub>, m. pt. –88° C (ref. 5), b. pt. 107° C (ref. 6).

The solid polymer reacts with 20 per cent aqueous hydrofluoric acid to give a mixture of silanes from SiH<sub>4</sub> to at least Si<sub>10</sub>H<sub>22</sub>. The yields are 25–35 per cent theoretical and the relative abundances of the species are similar to those obtained from silicon monoxide and HF (ref. 7) although less monosilane is formed. The polymer also reacts with amines and ethers to give complex mixtures of products, some of which retain long silicon chains.

Silicon difluoride is rather stable in the gas phase, apparently decaying only by collisions with the walls of the containing vessel. For example the pressure of SiF<sub>2</sub> fell from 0.1 mm to 0.05 mm in 2.5 min in a 5-l. flask at 25° C. No gaseous polymers were detected by mass spectrometry, but a polymer film appeared on the walls of the flask. Similarly, SiF<sub>4</sub> did not react in the gas phase with oxygen, boron trifluoride, phosphorus trifluoride or carbon monoxide, although in the case of oxygen the rate of decay increased greatly due to reaction on the walls of the flask. However, if silicon difluoride was condensed with any of these four gases at –196° C, reaction occurred and new products were obtained on warming to room temperature.

Under these conditions boron trifluoride formed a white silicon–boron–fluorine polymer, and two new compounds SiF<sub>2</sub>SiF<sub>2</sub>BF<sub>2</sub> and SiF<sub>2</sub>SiF<sub>2</sub>SiF<sub>2</sub>BF<sub>2</sub> (ref. 8) have been isolated. With phosphorus trifluoride the polymer was red and a mixture of volatile compounds, presumably of type Si<sub>n</sub>F<sub>2n+1</sub>PF<sub>3</sub>, was obtained which readily decomposed to perfluorosilanes and black PF polymers. Oxygen reacted with the silicon difluoride to give a clear liquid polymer mixed with a little (SiF<sub>2</sub>)<sub>n</sub>, and carbon monoxide gave a white, brittle solid polymer. Heating either the oxygen or carbon monoxide polymers gave a whole range of silicon oxyfluorides not previously described.

Thus, condensing silicon difluoride gas with another compound causes it to exhibit a far greater level of reactivity than is shown by the uncondensed gas or the polymer (SiF<sub>2</sub>)<sub>n</sub>. Preliminary work on the infra-red spectrum of SiF<sub>2</sub> trapped in an argon matrix suggests that at 20° K there is already some polymerization of the SiF<sub>2</sub> and that this is more extensive at 40° K. The spectrum is similar to that obtained by Milligan<sup>9</sup> for the dimerization of CF<sub>2</sub> to C<sub>2</sub>F<sub>4</sub> in a matrix, and is different from that observed for the (SiF<sub>2</sub>)<sub>n</sub> polymer at room temperature and the perfluorosilanes. Hence a type of unsaturation may exist in the low temperature con-

densed silicon difluoride polymers which could cause the observed high reactivity.

## BIOCHEMISTRY

### Stimulation of Steroid C-11 $\beta$ Hydroxylation in Adrenal Mitochondria by Cyclic 3',5'-Adenosine Monophosphate

ADENOSINE-3',5'-monophosphate (cyclic 3',5'-AMP) has been shown to stimulate steroid C-11 $\beta$  hydroxylations in rat adrenal homogenates<sup>1</sup> as well as the production of corticosterone from endogenous precursors in surviving rat adrenal sections<sup>2</sup>. In the latter instance, the effect of the cyclic nucleotide appeared to be related to enhancement of  $\alpha$ -glucan phosphorylase activity<sup>3</sup>, consequent NADPH production, and, possibly, to increased provision of endogenous steroid substrate<sup>4</sup>. In homogenates, however, stimulation of steroid C-11 $\beta$  hydroxylation did not seem to be dependent on glycogen phosphorylation, NADPH generation, or the availability of endogenous precursors<sup>5</sup>. Since steroid C-11 $\beta$  hydroxylase activity is associated with adrenal mitochondria<sup>6</sup>, experiments were undertaken to determine whether cyclic 3',5'-AMP was effective in isolated mitochondria. The data presented here reveal that the cyclic nucleotide was capable of stimulating C-11 $\beta$  hydroxylation of added progesterone and 11-deoxycorticosterone in purified adrenal mitochondria fortified with NADPH.

Adrenal glands were obtained under light 'Nambutal' (sodium pentobarbital) anaesthesia from young male rats (130–150 g) of an inbred Sprague-Dawley strain. The glands were immediately placed in a Petri dish kept on ice, dissected free of fat and connective tissue, and weighed. All subsequent procedures involved in the isolation of mitochondria were conducted at 0°–4°. Approximately 500 mg adrenal tissue were homogenized for 0.5 min in 8 ml. of 0.25 M sucrose using an all-glass homogenizer with a loose-fitting pestle. The sucrose was adjusted to pH 7.1 by addition of 40 mM *tris*-hydrochloride buffer (pH 7.4) to a final concentration of 0.8 mM. The suspension was then centrifuged at 700g for 10 min. Centrifugations were carried out in plastic tubes in a Sorvall refrigerated centrifuge. The supernatant was carefully removed with a dropping pipette and recentrifuged at 5,000g for 10 min. The supernatant and loosely-packed material from this centrifugation were discarded. The pellet was resuspended in the *tris*-sucrose medium with 8 strokes of a loose-fitting 'Teflon' pestle and centrifuged again at 5,000g for 10 min. The supernatant and loosely-packed material were again discarded. Thus far, the isolation procedure

Fig. 1. Radioactivity scanning patterns of thin-layer chromatograms, showing conversion of (4-<sup>14</sup>O)-progesterone to 11 $\beta$ -hydroxyprogesterone during incubation with rat adrenal mitochondria for 15–45 min. The incubation medium (3 ml) contained 0.2  $\mu$ mole progesterone (0.06  $\mu$ Ci), 1  $\mu$ mole NADPH, and mitochondrial suspension equivalent to 70–80 mg of adrenal tissue. Chromatographic origin is represented by 0 on abscissa. P, progesterone; 11 $\beta$ OHP, 11 $\beta$ -hydroxyprogesterone.

was similar to that described by Brownie and Grant<sup>7</sup>. The pellet was then resuspended in *tris*-sucrose and centrifuged at 10,000*g* for 10 min and the supernatant was removed as described before. Electron microscopy revealed that this pellet was composed mainly of intact mitochondria. Finally, the pellet obtained at 10,000*g* was resuspended in a buffer composed of 13 parts of 0.154 M NaHCO<sub>3</sub> and 37 parts of 0.154 M KCl. Protein was measured in aliquots of the mitochondrial suspension by the method of Lowry, Rosebrough, Farr, and Randall<sup>8</sup>.

The incubation mixture contained 0.2 ml. of mitochondrial suspension, 1  $\mu$ mole NaNADPH, 0.2  $\mu$ mole (0.05  $\mu$ Ci) of (4-<sup>14</sup>O)-progesterone or (4-<sup>14</sup>C)-11-deoxycorticosterone in 0.018 ml. 95 per cent ethanol, 48  $\mu$ moles NaHCO<sub>3</sub>, and other additives, made up to a final volume of 2 ml. with 0.154 M KCl. The amount of mitochondrial suspension added to each sample was equivalent to approximately 3–4 mg wet wt. mitochondria (0.5 mg mitochondrial protein), derived from 75 mg adrenal tissue. Methods of incubation, extraction, chromatography on thin-layer plates, measurement of radioactivity, and identification of the separated steroids have been described earlier<sup>1,9</sup>. Recovery of radioactive steroids carried through the extraction procedure exceeded 95 per cent.

The adrenal mitochondrial preparations were active in *O*-11 $\beta$  hydroxylations only when NADPH or NADP, glucose-6-phosphate, and glucose-6-phosphate dehydrogenase were added. In incubation periods varying in length from 15 to 45 min, the major metabolite formed from (4-<sup>14</sup>C)-progesterone was 11 $\beta$ -hydroxyprogesterone (Fig. 1). After 80 min, very small amounts of a more polar substance, which migrated more rapidly than corticosterone, were also noted. This may have been a *C*-18 hydroxylated product<sup>10</sup>. The absence of 11-deoxycorticosterone and corticosterone indicated that significant contamination with microsomal *O*-21 hydroxylase activity had not occurred. Cyclic 3',5'-AMP consistently and rapidly enhanced *O*-11 $\beta$  hydroxylation of progesterone in adrenal mitochondria. The conversion of progesterone to 11 $\beta$ -hydroxyprogesterone was stimulated to a greater degree by the cyclic nucleotide (2 mM) after incubation for 15–30 min than after 45 min, averaging 30 per cent in the former instances and only about 10 per cent in the latter (Table 1).

Since progesterone has been reported to inhibit *O*-11 $\beta$  hydroxylase activity in adrenal mitochondrial preparations<sup>11</sup>, the utilization of 11-deoxycorticosterone was also investigated. The major steroid formed was the *O*-11 $\beta$  hydroxylated product, corticosterone (Fig. 2, control). Subsequent experiments revealed that a portion of the radioactive material included under the corticosterone peak was 18-hydroxy-11-deoxycorticosterone. At a substrate concentration of 100  $\mu$ M and with an incubation period of 15 min, the basal rates of hydroxylation were similar for progesterone and 11-deoxycorticosterone; that is, about 20  $\mu$ moles  $\times 10^{-3}$  steroid converted per 100 mg adrenal tissue/h. However, the

Table 1. EFFECT OF CYCLIC 3',5'-AMP ON *O*-11 $\beta$  HYDROXYLATION OF (4-<sup>14</sup>O)-PROGESTERONE IN RAT ADRENAL MITOCHONDRIA

Incubation time (min)	Control 11 $\beta$ -hydroxyprogesterone formed ( $\mu$ moles $\times 10^3$ /100 mg adrenal)	Cyclic 3',5'-AMP 11 $\beta$ -hydroxyprogesterone formed ( $\mu$ moles $\times 10^3$ /100 mg adrenal)	Per cent increase	P value
15	3.04 $\pm$ 0.24	5.18 $\pm$ 0.29	21	< 0.01
15	5.22 $\pm$ 0.24	6.88 $\pm$ 0.27	22	< 0.01
30	8.27 $\pm$ 0.22	15.20 $\pm$ 1.10	33	—
30	9.64 $\pm$ 0.50	15.50 $\pm$ 1.10	27	—
45	14.49 $\pm$ 0.79	16.28 $\pm$ 0.22	11	0.05

The incubation medium (3 ml.) contained 0.2  $\mu$ mole progesterone (0.06  $\mu$ Ci), 1  $\mu$ mole NADPH, and 4  $\mu$ moles cyclic 3',5'-AMP (where indicated) in the presence of mitochondria from 70–80 mg adrenal tissue. The means  $\pm$  S.E.M. are shown where there were 4 samples, otherwise individual values are given. In the former instances, the P values are for the differences between control values and those obtained with the cyclic nucleotide.

stimulatory effect of cyclic 3',5'-AMP was greater with 11-deoxycorticosterone, varying from 50 to 75 per cent above the control level during a 15-min incubation period (Figs. 2 and 3). Furthermore, significant enhancement of corticosterone formation from 11-deoxycorticosterone could be produced with relatively low levels (0.5 mM) of the cyclic nucleotide (Fig. 3). This concentration appears to be lower than that required for stimulation of corticosteroid production in intact adrenal cells from the rat<sup>2</sup>.

The specificity of action of cyclic 3',5'-AMP has not as yet been thoroughly examined. The available data indicate that 5'-AMP also has a stimulatory effect on

Fig. 2. Radioactivity scanning patterns of thin-layer chromatograms showing conversion of (4-<sup>14</sup>O)-11-deoxycorticosterone to corticosterone during incubation with rat adrenal mitochondria for 15 min. The incubation medium (3 ml.) contained 0.2  $\mu$ mole 11-deoxycorticosterone (0.06  $\mu$ Ci), 1  $\mu$ mole NADPH, and mitochondrial suspension equivalent to 80 mg of adrenal tissue; 4  $\mu$ moles of cyclic 3',5'-AMP were added where indicated. DOC, 11-deoxycorticosterone; B, corticosterone.

Fig. 3. Influence of varying concentrations of cyclic 3',5'-AMP on conversion of (4-<sup>14</sup>O)-11-deoxycorticosterone to corticosterone during incubation with rat adrenal mitochondria for 15 min. Each point represents the average of 3 values. See legend to Fig. 2 for additional explanations.

steroid  $C-11\beta$  hydroxylations in adrenal mitochondria. Stimulation could not be produced with 2 mM 5'-ATP. The latter nucleotide has recently been shown to inhibit the stimulatory effect of mitochondrial swelling agents on pregnenolone synthesis from endogenous sources in adrenal mitochondria<sup>18</sup>.

The mechanism whereby cyclic 3',5'-AMP enhances steroid  $C-11\beta$  hydroxylations in adrenal mitochondria is unknown. Stimulation of NADPH generation has been suggested as a basis for the steroidogenic action of the cyclic nucleotide in the intact adrenal cortical cell<sup>8</sup>. However, steroid hydroxylation was not observed in adrenal mitochondria or homogenates<sup>8</sup> in the absence of NADPH or an NADPH-generating system, even when cyclic 3',5'-AMP was added in high concentration (4 mM). Possible explanations for the action of cyclic 3',5'-AMP in adrenal broken cell preparations include stimulation of the transport of steroid or co-factor across the mitochondrial membrane and direct activation of the steroid  $C-11\beta$  hydroxylase enzyme system. Effects of cyclic 3',5'-AMP on biological transport and on enzyme activities in other tissues have been described<sup>19</sup>. The relationship of the stimulation by cyclic 3',5'-AMP of  $C-11\beta$  hydroxylations in adrenal mitochondria and homogenates to the action of the cyclic nucleotide in the intact cell remains to be explored.

### Heterotopic Calcification of Human Nail and Hair

THE deposition of calcium salts in tissue other than osteoid, known as heterotopic calcification, may conveniently be divided into two distinct types: dystrophic calcification of localized areas which occurs in dead or degenerate tissue following injury, for example, mosquito oostegons, and metastatic calcification of apparently normal tissue due to a generalized upset of calcium and phosphorus metabolism and the draining of calcium from the bones as occurs in hyperparathyroidism.

In view of the discovery during the past few years that a wide variety of hard keratins may exist in a calcified form<sup>1-4</sup>, an examination has been made of human nail and hair for evidence of heterotopic calcification.

Using as a test for calcification the presence of calcium orthophosphate spacings in the X-ray diffraction pattern of keratin, 110 specimens of finger nail and 40 of hair

were examined for calcification, 50 of the nails and all the hair, with one exception, were selected from geriatric patients and the remaining nail specimens from persons who could be divided roughly into three categories: (a) healthy males and females 5-45 years of age whose nails appeared normal; (b) persons of category (a) but whose nails were abnormal in appearance, for example, in shape or contained white flecks, or were mechanically weak; (c) persons of category (a) but whose nail or nail-bed had suffered injury.

Although 16 per cent of the nails from geriatric patients showed strong calcium phosphate reflexions, these reflexions were absent in the X-ray diffraction patterns of all the hair samples. A beard hair, however, which emerged at intervals from an inflamed follicle (chin area of healthy male aged 33 years) showed strong calcium phosphate reflexions with considerable orientation (Fig. 1).

Nails from categories (a) and (b) showed no calcification, although sometimes very poor keratin reflexions were observed in (b). An examination of white flecks in nails, which are often associated with low serum albumin, supported the view that they are not due to calcification<sup>5</sup>. In category (c), three cases of calcification due to injury were found, an outstanding example being studied in greater detail. The nail (female aged 4 years), which, together with the bed, had been injured by crushing, was allowed to grow until it dropped off. The appearance of the nail at the point of discontinuity of growth was quite distinct, as is shown in the electron micrograph (Fig. 2). The X-ray diffraction photograph of this material showed very strong calcium phosphate reflexions, which were absent in undamaged nail of the same subject, and an electron diffraction pattern of calcium phosphate also was obtained. The amount of calcified keratin present was sufficient to enable a micro calcium determination to be made with a flame photometer, the results being as follows (per cent calcium): Normal nail of subject, 0.20; nail at point of severance, 7.2; control 1 (male aged 33 years), 0.26; control 2 (female aged 7 years), 0.35.

It is generally assumed that the calcium salt responsible for calcification is hydroxyapatite, and the percentage of calcium in the damaged nail corresponds to 18 per cent of this substance.

It has been established, therefore, that dystrophic calcification of nail and hair can occur as the result of damage to the nail bed or hair follicle. Calcification on ageing, however, does not occur in hair but is limited to

Fig. 1. X-ray diffraction pattern of hair from a beard. Copper  $K\alpha$  radiation. Distance 4.0 cm

nails, and, in view of the fact that bones can decalcify with age, could possibly be metastatic in nature.

We thank Drs. F. N. Bamford and R. K. MacQuish, who assisted with the provision of samples, and Miss R. Ballin, for the electron micrograph.

### Metabolic Activity of Monolayer Tissue Cultures of Human Thyroid

STUDIES of iodine metabolism by dispersed human thyroid cells have been reported by Pulvertaft *et al.*<sup>1</sup> Pastan<sup>2</sup> and Tong *et al.*<sup>3</sup> have reported similar studies on calf and sheep thyroid cells, respectively. The latter authors' findings suggest that the follicular structure of intact thyroid tissue is not indispensable for the formation of thyroid hormones. Kerkof *et al.*<sup>4</sup> have reported their interesting observation of the re-organization of the monolayers of thyroid cells in tissue culture into a structural pattern resembling cross-sections of intact thyroid tissue when thyroid stimulating hormone was included in the medium.

Initially, the present work was concerned with the question of the indispensability of the follicular organization of the thyroid cells, not only with regard to the formation of thyroid hormones, but also with the formation in the culture medium of larger molecules (peptide or protein) which show the immunological activity of thyroglobulin in the tanned red-cell agglutination inhibition test. At the same time, the specificity of such activities was tested by using an established cell-line as a control (ERK cells). Coombe *et al.*<sup>5</sup> have shown that the ERK cells are of human origin.

Thyroid glands were manipulated within a few hours after surgical removal. The cells were dispersed by trypsin according to the method described by Pulvertaft *et al.*<sup>1</sup> with minor modifications. The cells were cultured in 'Pyrex' babies' bottles using the following media with and without the addition of 10 per cent calf serum (containing 11.6  $\mu$ g iodine/100 ml.): (a) TCM-199 (Glaxo), which is iodine-free; (b) a mixture composed of balanced electrolyte solution, tryptic meat broth and lactalbumin hydrolysate (3.9–7.8  $\mu$ g iodine/100 ml.). Thyroid cells could not survive more than 3 passages, partly because of their increasing stickiness to glass and our consequent inability to strip them off with trypsin without causing cellular damage. Although some of the cultures survived for nearly 2 months, an established cell line was never obtained from the 20 human thyroids used in this work. Pulvertaft *et al.*<sup>1</sup> are the only authors who claim to have done so.

All the cultures were derived from pathological material, obtained at operation. Nine cases were classified as toxic diffuse goitre, 5 as toxic nodular goitre, 5 as non-toxic nodular goitre and one as Hashimoto's thyroiditis. It was noted that poor growth resulted from 2 toxic diffuse goitres, one toxic nodular goitre and the case of Hashimoto's thyroiditis. Thus the most consistent growth was obtained from the 5 cases of non-toxic goitre, but as the numbers were small this may not be a significant finding.

Five of the above thyroid cell cultures were used for metabolic studies (2 diffuse toxic, 1 nodular toxic, 1 nodular non-toxic, 1 auto-immune thyroiditis of the Hashimoto type).

When the monolayers had been developed (2–3 days), they were washed several times with buffered electrolyte solution and fresh medium was added. A number of bottles were kept for the detection of stable thyroglobulin 0, 24 and 72 h after this change. An increase in the tanned red-cell agglutination inhibition titre was taken as an indication of the synthesis of thyroglobulin-like material. The results of this titration were, however, doubtful because positive results were obtained in only a small number of the bottles where calf serum was added, but not in protein-free medium. On the other hand, evidence was obtained of the presence of proteolytic activity in thyroid cell culture medium as indicated by the breakdown of <sup>125</sup>I-labelled human thyroglobulin added *in vitro* (Assem<sup>6</sup>). The labelled material was incubated with samples of tissue culture medium TCM-199 (pH 7.1–7.4) in which thyroid cells had been growing, for 24 h at 37°C. The breakdown products were separated by dialysis at 4°C against tap water for 16 h and original and residual radioactivity was counted in a well-type scintillation counter. The results of a typical experiment are given in Table 1. The addition of denatured ox haemoglobin (1 per cent) and 'Trasyol', 100  $\times$  i. units/ml. (a proteinase inhibitor, Farbensfabriken Bayer A.G.) induced a little reduction in this proteolytic activity. The ERK medium, however, showed a similar activity. The occurrence of a small degree of degradation of labelled thyroglobulin in the controls which were unused media could be explained by the contamination of this preparation with proteolytic enzymes originating from thyroid tissue from which it was prepared.

Only one culture (derived from a toxic diffuse goitre), of 5 tested in this way, showed ability to concentrate <sup>125</sup>I when added to the medium as iodide, after 2–3 days growth. In this culture the ratio of cell to medium radioactivity was 1.6:1, while the ratio of cell radioactivity to number of cells was 8 times greater than in ERK

Table 1. DIALYSISABLE <sup>125</sup>I, AS PER CENT OF TOTAL RADIOACTIVITY AFTER INCUBATION OF <sup>125</sup>I-LABELLED THYROGLOBULIN FOR 24 h AT 37°C

Additions	Medium of ERK cells	Medium of thyroid cells Primary cultures	Sub-cultures	Control (unused culture medium)
None	43	40	33	1.5
'Trasyol'	33	28	20	13
Denatured ox haemoglobin	24	30	20	14

cultures. In contrast, the remaining thyroid cultures gave cell/medium radioactivity ratios from 0.1:1 to 0.4:1; not significantly different from that of the ERK cells (0.2:1). However, the cells of two of the thyroid cultures with low  $^{131}\text{I}$  uptake contained traces of thyroxine and probably triiodothyronine (as well as mono- and di-iodotyrosine), when examined by paper chromatography after pancreatic digestion. The culture media in which both thyroid and ERK cells had been growing contained minute traces of  $^{131}\text{I}$  in organic form (mainly as iodotyrosines).  $^{131}\text{I}$ -labelled thyroglobulin was detected in the medium of only one thyroid culture. This material gave a radioactive peak in the alpha-globulin region on electrophoresis, which was displaced towards the cathode on adding dilute Hashimoto serum containing thyroglobulin antibody. This particular culture was grown in the medium containing calf-serum, and the cells concerned did not concentrate  $^{131}\text{I}$ .

There was therefore suggestive but not conclusive evidence that the thyroid cells were making thyroglobulin-like compounds. A more definite finding was that these cells produced enzymes with proteolytic activity. Ability to make these enzymes was not, however, specific to thyroid cells, since they were also found in the ERK cultures. The presence of proteolytic activity in the medium would inevitably make the detection of thyroglobulin difficult by any technique.

### Nutritive Value of Nigerian Water Melon

WATER melon (*Citrullus vulgaris*) is cultivated in Nigeria principally for the semi-drying oil which is extensively used for cooking and may be used as a substitute for cotton seed oil. The seeds are also used as vegetable soup, but the flesh is never eaten.

The present work was undertaken to investigate the nutritive value of the seeds as a basis for future work. The analytical work has been concerned with proximate analysis, mineral composition and the determination of oxalic, hydrocyanic and phytic acid content.

The seeds were bought at different times from the market, dried overnight at 100° C, and finely ground. Crude protein, crude fibre, ash, ether extract and hydrocyanic acid were determined according to the Association of Official Agricultural Chemists' *Methods of Analysis*<sup>1</sup>. Potassium was estimated by flame photometry, other minerals by means of a photoelectric spectrometer, oxalic acid by the method of Dye<sup>2</sup> and phytic acid by the method of McCance and Widdowson<sup>3</sup>.

Table 1 shows a typical proximate analysis of the seeds. Table 2 gives the distribution of the major inorganic constituents and Table 3 the minor inorganic constituents, while Table 4 shows the oxalic, hydrocyanic and phytic

Table 1. PROXIMATE ANALYSIS OF NIGERIAN WATER MELON

0.8	0	000	41

acid contents. All determinations are based on percentage of dry matter.

The seeds are very rich in protein and serve as a protein supplement, forming one of the most important sources of protein in the Nigerian diet. Nearly 60 per cent of the seed consists of oil. The oil is used as a substitute for palm oil in cooking, and after the oil has been extracted the residue is wrapped in leaves and steamed to give 'oaks'.

The seed is a good source of energy, 100 g supplying about 566 calories. The ash content is high. The important dietary constituents of the ash are the calcium, phosphorus and iron contents. It is poor in calcium and iron but relatively rich in magnesium. The phosphorus content is very high. Of all the Nigerian seeds and vegetables analysed, water melon contains the highest phosphorus content. This gives a Ca:P ratio of 1:11. Although the ratio is unbalanced (1:2 is the satisfactory ratio), since it is taken along with other foodstuffs the satisfactory ratio could easily be met.

It is generally accepted that, under certain conditions, dietary calcium is precipitated in the intestine, resulting in reduced calcium availability, which restricts growth and even causes rickets. The two acids that are supposed to be responsible for this are oxalic and phytic acids. Furthermore, the lowering of the calcium by excretion as calcium oxalate takes place through the kidneys. Crystals of calcium oxalate are deposited in the uriniferous tubules in the form of granules or stones, leading to oxaluria.

Calcium determinations in foodstuffs are therefore of little significance from the nutritional point of view, unless taken in conjunction with oxalic or phytic acid content or both. Water-melon seeds contain negligible amounts of oxalic acid, but nearly half the phosphorus occurs as phytic acid. Nevertheless, the amount of non-phytic phosphorus is still appreciable.

Cyanogenesis has been extensively studied in many plants, chiefly because of the toxic effect that the deadly poisonous hydrocyanic acid produced could have on livestock. Hydrocyanic acid does not occur free, but combined with sugars to form an insoluble, non-toxic compound known as cyanogenetic glycoside. The water-melon seed does not contain any hydrocyanic acid.

The plant samples were analysed by Dr. A. L. Kenworthy, Horticulture Department, Michigan State University, East Lansing, and this work was supported, in part, by a Michigan State University International Programmes—Ford Foundation grant.

### Rat Liver Sorbitol Dehydrogenase

THERE has been considerable interest in the effect of various diets and hormones on liver enzymes. One of the problems related to the interpretation of the results is the dependence upon the method of reporting the data. This problem arises because various treatments cause changes in liver nitrogen content, liver cellularity, body-weight, and ratio of liver-weight to body-weight. Several considerations related to the reporting of results obtained after dietary and hormonal treatment have been discussed previously<sup>1,2</sup>. It would therefore be interesting if the

activity of one enzyme were to remain unaffected by these many treatments using any given method of reporting results. Such an enzyme might be useful as a control. This report will present the effects on the activity of liver sorbitol dehydrogenase activity of several treatments known to affect many liver enzyme activities. Sorbitol dehydrogenase does not appear to be related to any apparently important normal metabolic function of the liver during most regimens or hormonal treatments, and it may therefore serve as a control enzyme activity for most treatments.

All animals (male Sprague-Dawley rats) were maintained on diet or treatment for 5 days before being killed, when they weighed between 100 and 200 g. The basic diets have been described previously<sup>1</sup> and the hormone treatments were as follows: cortisone (5 mg/rat/day), hydrocortisone (5 mg/rat/day), and thyroxine (1 mg/rat/day) injected interperitoneally. All rats receiving hormone treatment were fed the glucose diet (85 per cent glucose, 25 per cent casein, 5 per cent corn oil, 4 per cent salts, 1 per cent vitamins). The rats were killed and bled, and the liver was removed and rapidly chilled. A portion of the liver was homogenized in 4 volumes of 0.14 M KCl centrifuged for 30 min at 20,000g at 0-4° C. The resulting supernatant solution was used for a protein determination<sup>2</sup>, thus both a total and soluble protein content were determined. The sorbitol dehydrogenase was assayed as follows: 1.0 ml. of *tris* buffer (0.1 M, pH 7.4), 0.8 ml. of water, 1.0 ml. of D-fructose (1.0 M), 0.1 ml. of DPNH (7.5  $\mu$ moles/ml.) and 0.1 ml. of enzyme (a '1 to 10' dilution of supernatant solution obtained as above). All activities were corrected for endogenous DPNH oxidation. All assays were conducted at 25° C using a Gilford Model 2000<sup>3</sup> multiple absorbance recorder. The results are reported as units per 100 g body weight, per g liver, and per mg liver protein (both soluble and total). One unit of activity is the amount of enzyme required to cause the oxidation of one  $\mu$ mole of DPNH in one minute at 25° C under the prescribed assay conditions. All reactions obeyed zero order kinetics up to five times the greatest activities reported.

In this investigation 32 liver enzymes were examined, but only sorbitol dehydrogenase behaved consistently in all treatments. Two liver phosphatases, six enzymes related to glycogenolysis, one enzyme related to lipid metabolism, five enzymes linked to the tricarboxylic acid cycle, three pentose phosphate shunt enzymes, three transaminases, three enzymes related to aromatic amino-acid metabolism, four urea cycle enzymes and four other enzymes related to amino-acid metabolism were measured in addition to sorbitol dehydrogenase. The sorbitol dehydrogenase activity of rats on various diets or hormonal treatments is reported on the basis of specific activity (activity per g liver protein), per g liver, and per 100 g body weight (Table 1). A high protein diet which has been shown to increase the activity of many liver enzymes<sup>4-6</sup>, had no effect on sorbitol dehydrogenase activity per 100 g body weight. The same was true of a high fructose diet<sup>4,6,10</sup>. The administration of the hormones which have been shown to cause marked alterations in liver enzyme activity, cortisone and hydrocortisone<sup>6-7,11-14</sup>, and thyroxine<sup>6,12-16</sup>, had no effect on sorbitol dehydrogenase.

It is interesting to note that none of the treatments studied affected the activity of liver sorbitol dehydrogenase per 100 g body weight. The fructose diet would be considered the most likely to affect the activity of this

enzyme, since fructose is a substrate for this enzyme, but this treatment had no effect. One or more treatments caused significant alterations in the sorbitol dehydrogenase activity compared with the high glucose diet when the results are reported as activity per g soluble liver protein, per g total liver protein, or per g liver. Thus, it appears that when the most desirable method of reporting results is per 100 g body weight, sorbitol dehydrogenase is an excellent reference enzyme to show that the changes in activity were not due to non-specific overall changes in all enzyme activities. In cases where the enzyme being measured is related to a function performed by the liver for the entire body, such as gluconeogenesis, urea synthesis, aromatic amino acid metabolism, etc., activity per 100 g of body weight may possibly be the best method of reporting results as it may reflect the relationship between need and activity<sup>1,2</sup>.

I thank E. H. Avery for his assistance. This work was supported in part by U.S. Public Health Service grant AM-04732.

## Isoenzymatic Nature of L-Glutamic Dehydrogenase of Higher Plants

ELECTROPHORESIS of albumins of mature seeds of *Vicia faba* on polyacrylamide gel, with subsequent location of L-glutamic acid dehydrogenase (L-glutamate:NAD oxidoreductase (deaminating) EC 1.4.1.2) (GDH), using a tetrazolium procedure, revealed that this enzyme could be separated into a number of isoenzymes. A preliminary investigation has been made of these isoenzymes together with an examination of their distribution within the seeds and seedlings of *Vicia faba* (broad bean) and *Pisum sativum* (pea).

Protein extracts were prepared from the sterile seeds, embryos or seedlings using 5 per cent (w/v) potassium sulphate-0.1 M phosphate buffer, pH 7.2 (2°); the supernatant from this extract was then saturated with ammonium sulphate (4°). The precipitate which appeared was redissolved in 5 per cent (w/v) potassium sulphate-0.1 M phosphate buffer, pH 7.2, and then dialysed against tap water for 18 h. The supernatant from this dialysis was then subjected to disk electrophoresis<sup>1</sup> using 6 per cent acrylamide as previously described<sup>2</sup>. GDH activity was detected by incubating the gels under aerobic conditions at 35° for various times in a solution containing the following, per ml.: L-glutamic acid, 5 mg; nicotinamide adenine dinucleotide (NAD), 1 mg; 5-methyl phenazine methosulphate (PMS), 0.1 mg; 3-(4,5-dimethyl thiazolyl-

Table 1. EFFECTS OF DIETS AND HORMONES ON ACTIVITY OF LIVER SORBITOL DEHYDROGENASE

Thyroxine	8	6.17 $\pm$ 0.35	20.1 $\pm$ 0.8	30.8 $\pm$ 1.6	24.9 $\pm$ 1.4

2)-2,6-diphenyl tetrazolium bromide (MTT), 0.5 mg; phosphate buffer 0.1 M, pH 6.5.

Electrophoresis of albumins of mature seeds of *Vicia faba* on polyacrylamide gel, followed by detection of GDH activity using the procedure described, revealed the presence of seven formazan bands, five strong and two weak with respect to formazan deposition (Fig. 1); the two weaker formazan bands are not seen on the photograph. Similar results have been obtained with albumins extracted from mature seeds of *Pisum sativum*.

The electrophoretogram shown in Fig. 1 raises two important issues: first, do the formazan bands represent GDH activity; and secondly, are these isoenzymes formed by the electrophoretic separation or during the extraction procedure?

Evidence that these bands do represent GDH activity can be summarized as follows: (1) formazan deposition does not occur on gels boiled after electrophoretic separation of the albumins; (2) if NAD, PMS or L-glutamic acid is omitted from the incubation mixture formazan deposition does not occur; (3) only very weak formazan bands develop when NADP is substituted for NAD in the incubation mixture, the GDH of corn leaves has been reported to be NAD specific<sup>4</sup>; (4) formazan deposition, due to NADH<sub>2</sub>-MTT-tetrazolium reductase (diaphorase), occurs at different sites on the gel to those described here for GDH activity and then only with prolonged incubation times. These results strongly suggest that formazan deposition is due to the initial activity of GDH.

Evidence, which is described here, suggests that the pattern shown in Fig. 1 is not formed as a result of the electrophoretic procedure used in the separation of the isoenzymes described. Isoenzymes 1-5 have been separated, located and afterwards eluted off polyacrylamide gel; these eluates, after concentration and a second electrophoresis, revealed only one strong band of GDH activity on the gel and they did not reproduce the full pattern shown in Fig. 1.

Attempts to alter the isoenzyme pattern of the mature seed by altering the extraction conditions have so far

failed. Extraction of mature seeds with either citrate, veronal or *tris*-hydrochloric acid buffers instead of phosphate buffer, followed by electrophoresis, show an isoenzyme pattern similar to that of Fig. 1. Crude phosphate buffer extracts, pH 7.2, of mature seeds or extracts, purified by dialysis or ammonium sulphate precipitation, likewise show a pattern identical to that of Fig. 1.

Of the amino-acids tested as substrates instead of L-glutamic acid, only L-aspartic acid, L-valine and L-threonine produced a pattern similar to that shown in Fig. 1, but formazan deposition was extremely weak in these instances.

Using the tetrazolium procedure already described changes in the isoenzyme pattern of the cotyledons, radicle and shoot have been detected as germination proceeds; these changes have been followed using sterile germinating seeds of *Pisum sativum*. The dormant cotyledons (embryo-free) possess six isoenzymes, 2-7 (see Fig. 1 for isoenzyme numbers). Isoenzyme 2 is characterized by weak formazan deposition, isoenzymes 3-7 showing strong formazan deposition. As germination proceeds the cotyledons show a gradual loss of activity, judged by formazan deposition, of the more positively moving isoenzymes which leads eventually to the presence of only isoenzyme 7, 21 days after planting. The dormant radicle possesses isoenzymes 1-7, all isoenzymes showing strong and equal formazan deposition; this contrasts with the pattern of the dormant cotyledons in which isoenzyme 1 is not detected and isoenzyme 2 is only weakly active as judged by formazan deposition. As germination proceeds, formazan deposition by the more positively moving isoenzymes of the radicle decreases to give only two formazan bands at 66 h after planting; eventually only one formazan band remains 21 days after planting: this band probably corresponds in position to isoenzyme 7 of the pattern of the mature seed. The dormant shoot, like the dormant radicle, also possesses all seven isoenzymes. In this case isoenzyme 7 is characterized by stronger formazan deposition than the other six. Again, as germination proceeds the more positively moving isoenzymes show a loss of formazan deposition which eventually leads to only isoenzyme 7 remaining 21 days after planting.

These results suggest that the GDH described here can be separated into a number of isoenzymes and that these different forms of the enzyme are not formed as a result of the methods of extraction or separation which have been employed. Different parts of the pea seed appear to have a specific GDH isoenzyme pattern which can change with age.

A better understanding of the part played by GDH in the maturing and germinating seed may give some clue as to the function of the GDH-isoenzymes in the various parts of the seed.

### Transfer of Radioactivity of Cholesterol-7 $\alpha$ -<sup>3</sup>H to Fatty Acids of Tissue Lipids *in vivo*

When randomly labelled cholesterol (either with carbon-14 or tritium) was fed to rats, a small but appreciable amount of the administered radioactivity could be recovered in the carcass fatty acids<sup>1</sup>. In both cases it was assumed that the label was due to incorporation of the

carbon atoms of the isopropyl group of the cholesterol side-chain into the isolated fatty acids. In the course of recent experiments involving cholesterol metabolism in baboons we administered cholesterol- $6\alpha$ - $^3\text{H}$  (5 mc.) to a male baboon (18 kg) which was killed 3 days later. The lipids of a number of tissues (liver, spleen, kidney, lung, adrenal) were extracted with chloroform-methanol 2:1 (ref. 2), separated by chromatography on silicic acid\* and assayed for radioactivity by liquid scintillation spectrometry.

An appreciable amount of radioactivity was detected in all the lipid classes. While most of the tritium was found to be present in cholesterol and cholesterol ester, as would be expected, we also detected considerable radioactivity in most of the other lipid fractions. Table 1 presents the percentages of recovered tritium radioactivity present in a few representative tissues. Maximum activity was usually found in the triglyceride or phospholipid fraction. The purity of the individual lipid fractions was established by thin-layer chromatography on 'Silica gel G'. In order to ascertain the site of the radioactive hydrogen, several of the more radioactive fractions of the liver and kidney lipids were subjected to trans-esterification by heating with 5 per cent  $\text{H}_2\text{SO}_4$  in methanol at  $70^\circ\text{C}$  for 4 h. The fatty acid methyl esters were extracted from the trans-esterification mixture with hexane and the absence of contamination by the original lipid fraction was confirmed by thin-layer chromatography. The data (Table 2) indicate that the  $7\alpha$  hydrogen of cholesterol had been transferred to the fatty acids of the various tissue lipid fractions being studied. Experiments are in progress to extend this observation to other species and to attempt to elucidate the mechanism of the transfer.

Table 1. RECOVERY OF TRITIUM IN TISSUE LIPID FRACTIONS

Lipid fraction	Percentages of recovered tritium in:				
	Liver	Kidney	Aorta	Lung	Adrenal
Cholesterol ester	62.7	11.4	15.5	—	60.2
Triglyceride	17.6	1.0	3.8	6.0	13.0
Free fatty acid	8.0	18.9	4.0	0.3	1.0
Cholesterol	5.4	61.0	50.0	90.0	1.0
Diglyceride	0.9	1.0	2.3	1.0	0.5
Monoglyceride	0.9	1.4	5.8	0.5	5.8
Phospholipid	3.8	5.1	14.2	2.1	7.1

Table 2. RADIOACTIVITY RECOVERED FROM FATTY ACIDS AFTER TRANS-ESTERIFICATION

Lipid fraction	Percentage of $^3\text{H}$ radioactivity recovered as fatty acid methyl ester in:	
	Liver	Kidney
Triglyceride	—	94
Diglyceride	—	78
Monoglyceride	57	61
Phosphatidic acid	71	—
Cardiolipin	76	71
Leucithin	42	70
Sphingomyelin	45	—
Cerebroside	—	79

## Growth of *Escherichia coli* NCTC 5928 in Relation to Enzymes in Vitamin B<sub>6</sub> Metabolism

Results have been obtained which indicate the presence in *Escherichia coli* NCTC 86 of pyridoxamine phosphate oxidase<sup>1</sup> and of pyridoxine phosphate oxidase<sup>2</sup>. These enzymes had previously been demonstrated in rabbit liver preparations<sup>3-5</sup>. These enzymes in *E. coli* NCTC 86 have been investigated in aqueous extracts obtained from acetone-ether dried cells (kindly supplied by the Lister Institute of Preventive Medicine, Elstree, Herts.), which had been grown for 18 h at  $37^\circ\text{C}$  on a casein-digest medium solidified with agar<sup>6</sup>.

The culture media were as follows:

A.  $\text{KH}_2\text{PO}_4$ , 9 g/L; Difco bactocaseitone, 5 g/L; trace of  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ ; distilled water; sufficient 5 N NaOH to bring the pH to 7.4.

B.  $\text{KH}_2\text{PO}_4$ , 9 g/L; Difco caseamino acids, 5 g/L; trace of  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ ; distilled water; sufficient 5 N NaOH to bring the pH to 7.4.

C. Simple salts medium<sup>7</sup>:  $\text{KH}_2\text{PO}_4$ , 9 g/L; ammonium sulphate, 2 g/L; D-glucose, 1 g/L; sufficient 5 N NaOH to bring the pH to 7.0.

In all cases,  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ , 0.2 g/L, was added after pH adjustment and sterilization.

The *E. coli* NCTC 5928 cells were produced at  $30^\circ\text{C}$  under aeration, collected, and afterwards dried with acetone-ether<sup>8</sup>. Aqueous extracts were prepared by extracting the cells overnight with distilled water (20 mg cells/ml. water) at  $3^\circ\text{C}$ , after which the suspension was centrifuged at 12,000g for 30 min at  $0^\circ\text{C}$ . The enzyme activities were determined on the supernatant cell-free extract.

To determine enzyme activity, reaction mixtures were made up with pyridoxamine phosphate (Pam P) or pyridoxine phosphate (Pin P) as substrate. The pyridoxal phosphate (Pal P) produced was determined by the phenylhydrazine procedure<sup>9</sup>, and protein was determined by a modification of the method of Lowry *et al.*<sup>10</sup>. Specific enzyme activities were expressed in  $\mu\text{g}$  pyridoxal phosphate formed/h/mg protein.

Table 1

Culture medium	Phase of growth	Specific activities ( $\mu\text{g}$ Pal P formed/h/mg protein)		Pin P ox. Pam P ox.
		Pyridoxamine phosphate oxidase measured at pH 10.1	Pyridoxine phosphate oxidase measured at pH 10.1	
Caseamino acids	Log	1.54	1.54	1.00
	Decl. growth	1.43	1.93	1.35
	Stat.	1.53	1.48	0.97
Simple salts	Log	0.92	1.92	2.09
	Decl. growth	1.50	3.25	1.96
	Stat.	1.50	2.75	1.65

It was found that cells of *E. coli* NCTC 5928 grown in an amino-acid medium (caseamino acids), containing an acid hydrolysate of casein as the sole source of carbon and nitrogen, possessed a significant amount of pyridoxamine phosphate and pyridoxine phosphate oxidase activities, whereas cells grown in a similar medium (bactocaseitone), consisting of a pancreatic digest of casein, had no similar activity. Cells grown in the simple salts medium were found to have marked activities for these enzymes.

The reason for these differences is a matter for speculation. Caseamino acids consist of a mixture of amino-acids, commercial casein having been completely hydrolysed by HCl, with the destruction of the tryptophan originally present in the casein<sup>11</sup>. Bactocaseitone contains a mixture of peptides and amino-acids resulting from the hydrolysis of casein by proteolytic enzymes from the pancreas<sup>12</sup>, with a high proportion of tryptophan<sup>13</sup>. Bactocaseitone also contains a number of substances, including pyridoxine, which originate from the non-protein impurities of the pancreatic enzyme preparations. These substances are destroyed in the HCl hydrolysis procedure.

It appears that the oxidases can be produced in cells grown in a medium containing either a mixture of amino-acids without tryptophan, or with  $\text{NH}_4^+$  ions as nitrogen source and D-glucose as carbon source. It is possible that tryptophan, at relatively high concentrations in the growth medium, may act as a competitive homologue for the formation of the active sites in the enzyme protein.

## PHYSIOLOGY

### Reflex Innervation of the Ankle Joint

In spite of its obvious importance in postural physiology and lower limb surgery, no specific study of the innervation of the ankle joint in relation to mechanoreceptor reflexes elicitable therefrom has been reported previously. For this reason, we have examined the innervation of 58 ankle joints in the cat with macroscopic, microscopic and neurophysiological techniques similar to those used previously in this laboratory for the knee<sup>1</sup>, temporo-mandibular<sup>2</sup> and laryngeal<sup>3,4</sup> joints.

**Extrinsic innervation.** The articular tissues on the posterior aspect of the ankle joint (capsule, ligaments and fat pad) have the densest innervation—through articular branches of the long saphenous, posterior interosseous and anterior tibial nerves; from the intramuscular nerves in the flexor digitorum muscle; and from a nerve plexus in the deep posterior fascia of the lower leg. The anterior aspect of the joint is supplied from the anterior tibial nerve. The medial aspect (and the deltoid ligament) is supplied from the posterior tibial nerve. The lateral aspect (and the related collateral ligaments) is supplied from the anterior tibial and interosseous nerves.

**Articular nerve endings.** Microscopic examination (with gold chloride, frozen silver and methylene blue techniques) of the terminations of the articular nerves in the tissues of the ankle joint reveals the endings to be similar in type to those in the knee joint<sup>1</sup>, although different in their relative proportions. Myelinated afferent fibres of medium size (8–12 $\mu$ ) in the articular nerves terminate in Type I and Type II corpuscles that are located on all aspects of the fibrous capsule of the joint. In the ankle, however, the Type II end-organs are relatively more numerous than in the knee joint<sup>1</sup>, so that the numerical relations of the Type I and Type II corpuscles are more like those in the temporo-mandibular joints<sup>2</sup>. Type II corpuscles are present also in the posterior fat pad at the back of the ankle joint, as is the case with the other joints<sup>1,2</sup>. Myelinated afferent fibres of larger diameter (up to 17 $\mu$ ) in the articular nerves innervate Type III corpuscles, which are confined to the joint ligaments (as in other joints<sup>1,2,5</sup>). Plexuses and free nerve terminals, present throughout the fibrous capsule, fat pad and the walls of the articular blood vessels at the ankle, constitute the Type IVa variety of articular nerve ending, and are supplied by small (less than 5 $\mu$ ) myelinated and unmyelinated afferent fibres in the articular nerves. Type IVb endings, confined to the

tunica media of the articular blood vessels, probably represent the terminations of unmyelinated, post-ganglionic sympathetic vasomotor fibres in the articular nerves.

No nerve endings of any type are present in the synovial tissue of the ankle joint—as is the case with all the other joints we have examined<sup>1–3,6</sup>. Likewise, there are no Pacinian corpuscles in the articular tissues of the ankle (or other<sup>7</sup>) joints.

**Mechanoreceptor reflexes.** Neurophysiological studies<sup>4,8</sup> show that the corpuscular end-organs are articular mechanoreceptors with differing behavioural characteristics. Type I corpuscles are slowly-adapting and Type II corpuscles are rapidly-adapting—both types having low thresholds. The Type III corpuscles are high threshold, slowly-adapting mechanoreceptors. The non-corpuscular Type IVa terminations provide the articular pain receptor system.

Passive movements of the skinned and tenotomized ankle joint in the intact, lightly anaesthetized animal activate the Type I and Type II corpuscles to produce reciprocally related polysynaptic reflex changes in motor unit activity in the leg muscles, identified by multi-channel electromyography<sup>4,8</sup>—dorsiflexion of the foot provoking gastrocnemius facilitation and tibialis anterior inhibition. The motor unit responses are rapidly adapting from the Type II corpuscles, and slowly adapting from the fewer Type I corpuscles. The Type III corpuscles are not activated, except at the extremes of joint displacement. Painful stimulation of the capsular tissues of the joint activates the Type IVa endings to produce polysynaptic reflex spasm of both flexor and extensor muscles in the leg.

The articular origin of the reflex responses in the leg muscles is confirmed by their suppression following articular neurectomy, local anaesthesia (with 1 per cent 'Lignocaine' solution) of the joint capsule, and electrocoagulation of the joint capsule. Similar reflex responses in the leg muscles can be provoked by direct mechanical stimulation of the joint capsule with varying intensities. With increasing barbiturate anaesthesia, the articular reflexes in the leg muscles are abolished before the monosynaptic stretch reflexes, elicited in the same muscles, disappear; and they can only be demonstrated at the early stages of such anaesthesia. The articular mechanoreceptor reflexes appear to operate polysynaptically through the  $\gamma$ -motoneurone loop, contributing thereby to the co-ordination of limb muscle tone in posture and movement.

We thank Mr. Johanna Kitau for his assistance.

### Basal Metabolic Rate in Developing Renal Hypertension

THE development of renal hypertension in the rat, induced by means of partial occlusion of one renal artery and contralateral nephrectomy, has been reported to be associated with transient elevation of cardiac output<sup>1</sup>. The experiments reported here were designed to test the possibility that this transient rise in cardiac output is due to a concurrent increase in metabolic rate.

A spirometer was constructed to hold two rats in separate compartments, each of which could be coupled independently to a closed circuit which included an air pump and a carbon dioxide absorber. The gas within the circuit was pumped round at a rate of 1 l./min. After initial washing through of the system with oxygen, further oxygen was introduced into the system in successive 5-ml. amounts and the absorption time measured by observing through a microscope eyepiece the movement of a fine wire attached to a rubber tambour, 13 cm in diameter, included in the circuit. Negligible pressure changes occurred in the closed circuit. The whole apparatus was immersed in a water bath and the observations made at a temperature of between 26° and 29° C, since it had been shown that oxygen uptake was constant above 26° C. Female Wistar albino rats weighing initially 200-220 g were conditioned in pairs daily to the spirometer for seven days. Three measurements of uptake of oxygen were then made on separate days over a week, at the end of which time the animals were subjected to an operation consisting of the application of a silver clip to the right renal artery together with removal of the left kidney. The clip in the case of one member of a pair had a gap 0.25 mm wide (experimental group) and in the other 0.5 mm (control group). Serial observations of uptake of oxygen were then made every 2-3 days for four weeks. After each measurement of uptake of oxygen the systolic blood pressure was measured by a tail plethysmographic method under light ether anaesthesia.

Eight rats in the control group remained normotensive throughout (blood pressure, less than 140 mm mercury), whereas ten rats in the experimental group developed mild to severe hypertension (blood pressure, 140-260 mm mercury) (Fig. 1). A slight post-operative fall in mean oxygen uptake occurred in both groups but there was no significant difference between the groups at any time after operation. Statistical analysis of the figures showed that the scatter was such that a difference of 8 per cent in oxygen uptake between the experimental and control groups would have been detected. No difference between the weight changes in the two groups occurred.

These results indicate that the mean increase of 25 and 35 per cent in cardiac output observed in rats developing this form of renal hypertension in the first two five-day periods after operation<sup>1</sup> is most unlikely to be due to an increase in tissue oxygen requirements. The further possibility has been suggested by Borst<sup>2</sup> that haemodilution could be responsible for the increase in cardiac output. The haematocrit in these animals developing hypertension is not reduced by more than 0.5 per cent below that in the control animals<sup>3</sup> and it is very improbable that such small changes could be responsible. Thus the transient increase

in cardiac output observed in the development of renal hypertension is not readily explicable on the basis either of increased metabolic rate or of haemodilution. Such an increase beyond the metabolic requirements of the tissues might be expected to stimulate autoregulation of peripheral tissue perfusion and may be of importance in the pathogenesis of renal hypertension as suggested by Ledingham and Cohen<sup>4</sup>.

I thank Prof. J. M. Ledingham, Dr. R. D. Cohen and Dr. J. R. Hill for their advice and Mr. F. Palmer for technical help.

### Endothelial Vesicles and Protein Transport

THE physiological mechanism involved in the transfer of water, solutes and macromolecules across endothelium remains obscure<sup>1,2</sup> though it has been subjected to considerable investigation. When permeability is increased, endothelial gaps, believed to be intercellular, are found in the endothelium<sup>3-5</sup>. In electron microscopic examinations, tracer particles, injected into the blood stream, aggregate in the gaps, which are the sites of plasma leakage and the stigmata and stomata of light microscopy<sup>6,7</sup>. However, in physiological states, with the exception of lymphatics<sup>8,9</sup> and such special vascular beds as the sinusoidal vessels of the liver<sup>1,10-12</sup>, spleen<sup>14</sup>, bone marrow<sup>13,15</sup> and frog heart<sup>16</sup>, gaps do not occur in vascular endothelium. This report concerns the finding of a new type of vesicle in endothelium, and it is considered that these specialized micropinocytotic vesicles could be related to protein transport in the lymphatic and vascular endothelium of frog tissues.

Queensland green tree frogs (*Hyla caerulea*) were pithed or decapitated prior to the removal of the interdigital webs of the hind limbs, and portions of the tongue, mid-gut, lung and abdominal skin. Tissues were cut into small blocks, fixed for 2-18 h in 1 per cent osmium tetroxide, buffered according to Zetterqvist's method<sup>17</sup> and then dehydrated in ethanol and embedded in 'Araldite'. The sections were cut on an LKB (type 4800 A) ultramicrotome, mounted on copper grids, stained with lead<sup>18</sup> and 1 per cent uranyl acetate in ethanol and then examined in a Siemens Elmiskop I electron microscope.

In the webs, large cleft-like lymphatic spaces which never contained blood were regularly found. They were lined by a layer of endothelial cells with an incomplete basement membrane. The ultrastructure of the endothelium was similar to previous descriptions<sup>9,19</sup>. An intercellular gap was observed only once.

Two morphologically distinct types of vesicle were present in the endothelium (Figs. 1 and 2). The micropinocytotic vesicles and caveolae, first described by Palade<sup>20</sup> in vascular endothelium, were relatively numerous; these vesicles were round or oval and for the most part 600-1000 Å in diameter, though more elongated or even multilocular forms were observed. These vesicles and pits were bounded by a well-defined membrane immediately within which a light grey zone of variable thickness faded centripetally. The thickness and density of this zone often varied around the circumference of the vesicle.

Of much less frequent occurrence were the dense micropinocytotic vesicles. These were round or oval and varied in size from 600 to 1600 Å, most being 800-1200 Å. The limiting membrane was frequently denser than the foregoing type of vesicle. Inside the limiting membrane was a zone of granular or fibrillary material 100-300 Å

Fig. 1. Stippled, tight clip; white, loose clip

Fig. 1. Lymphatic endothelium containing a dense vesicle (DV) and an infolding of the basal surface of the plasma membrane of similar structure (DC). Vesicles (V) and caveolae (C) of light density are illustrated. ( $\times 51,500$ )

Fig. 2. Lymphatic endothelium with two dense caveolae (DC) on the luminal surface. Vesicles (V) and caveolae (C) of light density, an unidentified dense body (D), endoplasmic reticulum (R) and nucleus are illustrated. The lumen is at top. ( $\times 51,500$ )

thick. Yet the most striking feature was a layer of radially arranged fibrillary material approximately 150–200 Å wide on the cytoplasmic surface (Figs. 1 and 2). Small vesicles often had a wider zone of material lining the cavity, but they may not have been sectioned through the centre. At low magnifications they were recognisable because of this overall density which contrasted with the more numerous vesicles of low density. This specialized structure of the wall was seen in slight indentations of the plasma membrane as well as in distinct caveolae and vesicles. At times only part of the wall of a vesicle was so modified.

The endothelium of blood capillaries, venules, arterioles and small arteries also contained the two morphologically distinct types of vesicle. As in the lymphatic endothelium, dense vesicles were less frequent than the type originally described by Palade<sup>19</sup>.

The less-dense vesicles are well-documented structures and are known to occur in endothelium, pericytes and smooth muscle cells. They have been extensively investigated for the possibility of transfer of fluid, solutes and larger molecules across the vessel wall, but at present no conclusive evidence has been forthcoming<sup>1,2</sup>.

The dense vesicles have been observed in the cells of the proximal convoluted tubules in bat kidney, in the liver cells of rats and chickens and also in Kupffer cells<sup>20–22</sup>. Roth and Porter<sup>23</sup> specifically stated that the dense vesicles in these sites were different from and should not be confused with the pinocytotic vesicles of endothelium. They were under the impression that dense vesicles did not occur in endothelial cells, for the vesicles had not been observed previously in endothelium. In the past they could have been overlooked in mammalian tissues, for they may

not be so numerous as in amphibia which have a proportionately greater daily turnover of fluid and protein from blood to lymph<sup>22–24</sup>.

As yet, the functional significance of the two types of vesicle in lymphatic and vascular endothelium is uncertain. However, Roth and Porter have provided evidence that dense vesicles play an important part in the uptake of protein by the developing oocyte of the mosquito in the formation of yolk granules<sup>24–25</sup>. It was suggested that the bristle border on the cytoplasmic surface was responsible for the invagination of the plasma membrane in the formation of pits and vesicles or, what is more likely, for the selectivity of uptake and carriage by the vesicles<sup>24</sup>. So, if these vesicles are specifically concerned with the uptake of protein in other sites, they probably have a similar function in endothelium. Moreover, in endothelial cells they could be concerned with protein transfer across the vessel wall, be it vascular or lymphatic.

The present unconvincing evidence for the role of pinocytotic vesicles (of the less-dense variety) in the transfer of tracer particles across endothelium<sup>1,2</sup> may be due in part to the selectivity of vesicles and to the physical and chemical nature of the injected particles. Therefore the permeability of lymphatic and blood vessels should be investigated with the view to determining the functional significance and selectivity of these two types of endothelial vesicle.

I thank Dr. E. H. Marcor for his advice.

### Anti-progestational Activity of Rutin on the Rabbit Uterus

A DIET containing 0.4 or 1.0 per cent of rutin, a flavonol glycoside with vitamin P activity, has been shown to have no effect on reproduction<sup>1,2</sup>. However, Cutting *et al.*<sup>3</sup> observed that a diet containing 0.1 per cent rutin significantly impaired the fertility of female mice. Therefore,

using carbonic anhydrase determination in the uterine endometrium as an indicator of the progestational proliferation in Clauberg rabbits<sup>4</sup>, an attempt was made to elucidate whether or not rutin is capable of affecting the progestational proliferation of the rabbit endometrium.

Experiments were performed on immature albino female rabbits weighing approximately 1.5 kg. Following the Clauberg method<sup>4</sup>, all the animals were primed with a subcutaneous injection of 5 µg oestradiol once daily for 6 days. This was then followed by simultaneous administration of progesterone and rutin once daily for 5 days. Progesterone dissolved in sesame oil was given subcutaneously and rutin was administered either subcutaneously or orally as a thin alkaline saline solution. The standard dose of progesterone was 1.0 or 2.0 mg per animal and the rutin doses varied as indicated in Table 1. The rabbits were killed two days after the last dose. The endometrium was dissected from the isolated uteri and homogenized in cold distilled water. The supernatant of the homogenate was tested for carbonic anhydrase activity by the method of Miyake and Pincus<sup>5</sup>, the activity being expressed in terms of enzyme units/g wet weight of the endometrium<sup>7</sup>.

As indicated in Table 1, a standard dose of progesterone (2 mg or 1 mg) alone exerted a typical activation of endometrial carbonic anhydrase. However, when given subcutaneously, with 2 mg progesterone, rutin in amounts ranging from 0.01 to 0.1 mg appeared significantly to inhibit the endometrial response; 0.01 mg causing a 39 per cent, 0.02 mg a 33 per cent, and 0.1 mg a 28 per cent inhibition. Likewise, a total dose of 0.05 mg rutin also appeared unequivocally to prevent the effect of 1.0 mg progesterone. However, in doses totalling more than 1.0 mg, there was no significant difference between the endometrial enzyme responses to progesterone with and without rutin. In an attempt to show the effect of rutin itself on endometrial enzyme activity, rutin alone was injected subcutaneously in doses of 1.0–10.0 mg per animal. No significant increase in the endometrial enzyme above the control was found. In other experiments (Table 2), when rutin was administered orally in doses of 0.01–100 mg per animal along with 2 mg of progesterone, rutin-treated animals responded by showing a marked increase

in the activity of endometrial enzyme. The degree of increase was essentially the same as that of the enzyme activation characteristic of progesterone alone.

From the present finding that in the rabbit rutin exhibited a weak inhibition of the increase in endometrial carbonic anhydrase caused by progesterone, it seems that rutin acts as an antiprogestational agent, presumably due to a direct action of rutin itself on the uterus.

I thank Prof. T. Suzuki for his advice. This work was carried out with the support of a grant from the Population Council, Inc., New York.

## PHARMACOLOGY

### Metabolic Investigations on Pristinamycin

PRISTINAMYCIN is a new antibiotic obtained from *Streptomyces pristinae spiralis*, a *Streptomyces* isolated from a soil sample taken at San Carlos (Cordoba) in Argentina<sup>1</sup>. It is made up of several components and belongs to the family of synergistic antibiotics which includes streptogramin, stephydomycin and ostreogrycin. Chromatographic analysis has shown that pristinamycin is a mixture of two groups of components, the proportions of which vary within certain fixed limits:

Group I	{ Pristinamycin I <sub>A</sub> Pristinamycin I <sub>B</sub>	15–30 per cent 5–10 per cent
Group II	{ Pristinamycin II <sub>A</sub> Pristinamycin II <sub>B</sub>	45–60 per cent 5–10 per cent

Some of these components resemble those of the other antibiotics mentioned, but pristinamycin may be differentiated from these by its antibiotic activity, which results from the whole complex of different constituents<sup>2</sup>.

Pristinamycin, which is administered orally, is highly active against *Staphylococcus aureus*, including strains resistant both to benzylpenicillin and to erythromycin, *Streptococcus pyogenes* and *Streptococcus pneumoniae*. It also shows high activity against strains of *Streptococcus faecalis* and *Haemophilus influenzae* and against *Neisseria* resistant to lincomycin<sup>3</sup>.

Clinical use<sup>4–6</sup> of pristinamycin has prompted us to examine its degradation in the human body, and as a first approach we tried to identify any metabolite originating from one of the main components of pristinamycin which is called constituent I<sub>A</sub> (or 12,535 E.P.), a cyclopeptide of the formula:

This compound is identical to factor B in the ostreogrycin complex, described by Eastwood, Snell and Todd<sup>1\*</sup>.

For the systematic investigation of the degradation products which may be excreted in human urine, it has been necessary to synthesize and to resolve the unusual amino-acids present in constituent I<sub>A</sub>; furthermore, the

The following abbreviations are used: Pic, 3-hydroxypicolinic acid; Thr, L-threonine; But, D- $\alpha$ -aminobutyric acid; Pro, L-proline; Damaphic, L-para-dimethylamino  $\beta$ -methylphenylalanine; Pip, 4-oxopipicolic acid; Phegly, L- $\alpha$ -phenylglycine; Gly, glycine.  $R_F^1$ :  $R_F$  by thin-layer chromatography on silica gel with methanol.  $R_F^2$ :  $R_F$  by paper chromatography with butanol-acetic acid-water (7-1-2).  $R_F^3$ :  $R_F$  by paper chromatography with isoamyl alcohol-pyridine-water (25-25-50).

linear heptapeptide corresponding to the opening of the aforementioned cyclic lactone, and several oligopeptides, as indicated in Table 1, have been synthesized<sup>11</sup>.

The search for the metabolites in urine was performed as follows:

(1) For the untransformed constituent  $I_A$ .

This investigation was carried out by thin-layer and paper-chromatography as well as by bioassay<sup>12</sup>.

(2) For compounds arising from possible degradation of the cyclopeptide.

The search for the amino-acids was performed by chromatography of the urines by means of a Technicon automatic amino-acid analyser. Synthetic amino-acids and urine collected immediately before the ingestion of pristinamycin were used for reference purposes.

The assay, of peptides which could occur from cleavage of the cyclopeptide, was carried out by two techniques: paper chromatography was used for comparison of urines with blanks containing synthetic peptides, and thin-layer chromatography on silica gel was used for a systematic search for peptides. Comparative chromatograms of the urines to be investigated, blanks, and urines with added pristinamycin, were developed. Parallel areas were cut out on each plate, silica gel corresponding to each area was collected and eluted and the eluate was hydrolysed. Quantitative assays of the hydrolysates were then performed in order to determine the presence or absence of peptides and to evaluate their qualitative composition.

(3) For modified hydrolysis products.

The results of the foregoing investigation suggested that a search be made for compounds the structure of which resulted from a modification of the metabolites derived from the cyclopeptide. Paper chromatography, especially on anion exchange paper, was used for this work.

A complete survey of the urines of volunteers, who ingested 4 g of pristinamycin over 32 h in four administrations, gave the following results:

(1) About 10 per cent of constituent  $I_A$  of pristinamycin was excreted without transformation.

(2) No single amino-acid derived from constituent  $I_A$  was excreted in any detectable amount in urine.

(3) No peptide metabolite could be identified by comparison with the synthetic peptides listed in Table 1. These include the linear heptapeptide which would result from opening the macrolactone and correspond to theoretical hydrolysis fragments of constituent  $I_A$ .

(4) However, some metabolites could be detected in small amounts; ultra-violet absorption and fluorescence showed that they were related to 3-hydroxypicolinic acid. The main product was identified as a derivative of 3-hydroxypicolinylglycine, but even this peptide dis-

appears from the urine 6 h after the absorption of pristinamycin.

### Significance of Smoking in Investigations of Urinary Excretion Rates of Amines in Man

In the determination of amphetamine ( $T_R$  9 min) by a gas-liquid chromatographic method<sup>1</sup>, an additional peak ( $T_R$  26 min) was observed in the extracts from urine of some but not all subjects; only subjects who smoked gave this latter peak. In smokers, large differences were observed in the 'apparent amphetamine' content of the urine determined by a methyl orange complexing method (using 1:2 dichloroethane as the extracting solvent, a solvent wash with borax pH 9.2 and measurements read at 540 m $\mu$ ), and the amphetamine content determined by gas-liquid chromatography<sup>1</sup> (Fig. 1).

The additional component with a  $T_R$  of 26 min in the urine of smokers was shown to be nicotine by gas-liquid chromatography, thin-layer chromatography and also by the infra-red spectrum of the isolated base.

The sum of the amphetamine content and the nicotine content, both determined by gas-liquid chromatography, gave values comparable to the 'apparent amphetamine' content determined by the methyl orange technique.

Fig. 1. True ( $\square$ ) and apparent ( $\Delta$ ) rates of amphetamine excretion in the urine of a smoker as determined by gas-liquid chromatography for the former, and by the methyl orange procedure for the latter. The rate of nicotine excretion ( $\circ$ ) in the same urines is also indicated

The formation of complexes with methyl orange is a commonly used method for the determination of amines in urine and other biological fluids<sup>1-4</sup>. However, there seems to be little indication that only non-smokers have been used for investigations in man, although it has been reported<sup>1</sup> that nicotine complexes with the dye in the methyl orange technique. We have found that in many of the diverse methyl orange methods<sup>1-4</sup> the nicotine-methyl orange complex partitions into the organic phase and thus interferes with the determination of amines in biological fluids by these methods.

Using a gas-liquid chromatographic method for the determination of nicotine, we found that the rate of nicotine excretion in urine is influenced by the pH of the urine (see also ref. 9). Subjects smoking 20 cigarettes a day at fairly regular intervals excreted 0.1-4.3 (mean 1.0)  $\mu\text{g}$  nicotine per min under normal conditions, 0.4-13.0 (mean 5.0)  $\mu\text{g}$  nicotine per min when the urine was acidic after the oral administration of ammonium chloride, and less than 0.1  $\mu\text{g}/\text{min}$  when the urine was alkaline after the oral administration of sodium bicarbonate.

Usually 'blank' values for urine by the methyl orange method are obtained before the method is used for the determination of drugs in urine. Obviously the 'blank' value for a smoker will depend on his smoking habits and the pH of the urine at the time of collection; this value may have little significance when applied as a correction at the time of the determination of the drug.

It is our opinion that smokers should not be used in urine excretion investigations of basic drugs unless nicotine has been shown not to interfere with the assay procedure adopted.

### Biological Half-lives of the Antibiotic Lincomycin Observed in Repetitive Experiments in the same Subjects

SOME information on the disappearance half-time of lincomycin (the registered trade-mark of the Upjohn Company is 'Lincocin') has been reported by Ma, Lim and Nodine<sup>1</sup> and by Wagner and Alway<sup>2</sup>.

We now wish to report biological half-lives of lincomycin estimated from serum levels obtained after oral administration of lincomycin hydrochloride in doses equivalent to 0.5 g lincomycin base. In three experiments (I, II and III) doses were administered to the same panel of six adult male subjects at 0, 7, 28, 35, 84 and 91 days. In experiment IV a panel of sixteen adult male subjects received doses one week apart. Table 1 lists the formulations and their code numbers used in the four experiments.

Experiments II, III and IV were cross-over studies in which half the subjects received one formulation and the other half received the other formulation the first week; the formulations being reversed with respect to

Table 1

Expt.	Code	Type
I	1	Hard-filled capsule containing only lincomycin hydrochloride.
II	1	Ibid.
II	2	Aqueous solution formed by dissolving the above capsule contents in one-half glass of water.
III	3	Hard-filled capsule containing lincomycin hydrochloride, lactose, talc, and magnesium stearate.
III	4A	Pediatric solution containing lincomycin hydrochloride, preservatives, sweetening agents and flavouring agents.
IV	3	Ibid.
IV	4B	Pediatric solution—same formula as 4A but different lot.

subjects the next week. In each experiment blood samples were obtained at zero time (just before administration) and at 1.5, 3, 4.5, 6, 8, 10, 12 and 14 h after administration. Serum was collected and frozen. Antibiotic concentrations in serum were determined by the agar diffusion method with *Sarcina lutea* ATCC 9341 as the test organism. The method was the standard cylinder plate procedure of Hanks *et al.*<sup>3</sup>, as modified by Vavra *et al.*<sup>4</sup>.

Disappearance rate constants were calculated in the usual way<sup>5</sup> by first plotting the serum levels against time on semilogarithmic graph paper. All terminal points which appeared randomly distributed about a straight line were used. The method of least squares was employed using an IBM '1620' computer programme. The computer converted the serum levels to their logarithms (base 10) and printed out the slope of the least squares line. Division of the slope into 0.301 ( $\log_2$ ) gave the biological half-life,  $t_{1/2}$ .

The biological half-lives calculated from serum levels observed in repetitive studies in the same six subjects are shown in Table 2.

The biological half-lives calculated from serum levels observed in Experiment IV are shown in Table 3. The median half-life is 4.8 h, which agrees quite well with the overall median half-life of 4.6 h obtained in the other three experiments.

Analysis of the data shown in Tables 2 and 3 provides little, if any, evidence that the biological half-life of lincomycin changes significantly with time when repetitive oral doses are given at weekly or less frequent intervals.

Ma, Lim and Nodine<sup>1</sup> reported a longer disappearance half-time of lincomycin after the last dose than that observed after the first dose when lincomycin hydrochloride was administered intramuscularly every 12 or 24 h to human subjects on a multiple-dose regimen. The difference in apparent average half-lives was not statistically significant, but they suggested that "further studies or the further analysis of available data should be carried out elucidating this point".

However, 'disappearance rates' and 'half times' reported by these authors following multiple doses were estimated from serum concentrations observed at 1 and 12 h or 1 and 24 h after administration. Our analysis of lincomycin serum levels following intramuscular administration indicates that part of the dose is absorbed over at least a 12 h period. Hence, Ma, Lim and Nodine estimated half-lives from data containing points in the absorption-tissue distribution phase, and not really a set of points randomly

Table 2. BIOLOGICAL HALF-LIVES (IN HOURS) OF LINCOMYCIN OBSERVED IN REPETITIVE STUDIES IN THE SAME SIX ADULT MALE SUBJECTS

Study	Date	Subject						Date Median
		H	B	O	K	B	P	
I	18/3/64	—	0.13*	—	5.35*	—	4.63*	5.26

	31/3/64	5.90*	5.02*	4.80†	4.55†	4.10†	4.56*	4.68
III	19/5/64	7.86†	8.43†	5.15†	4.24†	4.59†	4.47†	4.87
	26/5/64	9.09†	4.90†	4.22†	4.09†	4.18†	4.14†	4.20
Subject median		7.86	5.52	4.80	4.56	4.47	4.51	4.60

\* Formulation 1 (median half-life = 5.29 hours)

† Formulation 2 (median half-life = 4.38 hours)

‡ Formulation 3 (median half-life = 4.36 hours)

§ Formulation 4A (median half-life = 4.37 hours)

Table 2. BIOLOGICAL HALF-LIVES (IN HOURS) OF LINCOMYCIN OBTAINED IN CROSS-OVER EXPERIMENT IV IN SIXTEEN ADULT MALE SUBJECTS

Group of subjects	Cross-over No. 1	
	19/5/64	20/5/64
	3*	4B*
1-4	5.87	5.40
	6.63	4.43
	3.77	3.76
	4.19	3.62
	4B	3
5-8	4.93	5.46
	5.31	5.24
	4.78	4.74
	3.44	4.41
Median half-life	4.86	4.58
Cross-over No. 2		
	20/5/64	27/5/64
	3	4B
9-12	4.25	4.18
	4.50	4.81
	4.02	3.77
	5.27	7.64
	4B	3
13-16	5.71	11.5
	4.62	5.81
	5.20	5.13
	8.80	3.52
Median half-life	4.66	5.31

\* Formulation code; see Table 1.

distributed about a straight line on semilogarithmic paper. If absorption is still proceeding when  $t_1$  is estimated, the estimated  $t_1$  will be higher than the true value<sup>1</sup>. Re-evaluation of their data does not suggest an increase in half-life following a multiple-dose regimen.

Assuming a disappearance rate constant estimated from data obtained after the first dose, Wagner and Alway<sup>2</sup> made predictions of serum levels of lincomycin which agreed reasonably well with serum levels observed after multiple intravenous injections.

Further examination of Tables 2 and 3 shows that median half-life is essentially independent of the specific formulations involved. The rate constant for disappearance (or the biological half-life) of a drug in the body would be expected to be independent of dosage form effects if the data were properly collected and interpreted<sup>3</sup>. After the solution and capsule treatments, the median biological half-lives were: Experiment II, 4.38 and 4.55; Experiment III, 4.87 and 4.86; and Experiment IV, 4.80 and 4.99, respectively. Hence, in two of three experiments, the capsule yielded a very slightly greater median half-life.

In addition, fitting of the serum level data to a three-compartment model (Model I, ref. 5) indicated that first-order rate constants for appearance of lincomycin in the blood were not significantly different after the capsules, compared with the solutions. These additional analyses gave us confidence that absorption was, for all practical purposes, complete at the times the half-lives were estimated.

We thank C. G. Chidester, L. K. Schadewald and R. L. Yeager, who assisted with the microbiological assays, and Dr. I. J. Martens for his supervision of the clinical trials.

### Influence of the Substantia Nigra on the Concentration of 5-Hydroxytryptamine and Dopamine of the Striatum

EVER since the finding that certain of the basal ganglia contain relatively high concentrations of dopamine (3-hydroxytyramine)<sup>1,2</sup> there has been a growing interest in the possible role of this amine in the functioning of these structures of the extrapyramidal system<sup>3</sup>. Hornykiewicz *et al.* have demonstrated the virtual absence of this amine from the caudate nucleus and putamen of patients dying from Parkinson's disease<sup>4,5</sup> and, even though the concentrations of noradrenaline<sup>6</sup> and 5-hydroxytryptamine<sup>6</sup> in these regions of the brain are substantially below normal values, the decrease in the concentration of dopamine is greater and, in contrast, uninfluenced by administration of monoamine-oxidase inhibitors<sup>7</sup>.

In work concluded some time ago in our laboratories it was possible to show that experimental lesions in the ventromedial tegmental area of the brain-stem of rhesus monkeys result eventually in the loss of dopamine and noradrenaline from the corpus striatum<sup>8,9</sup>. Only those lesions that resulted in a major loss of cells of the substantia nigra produced a fall in the concentration of the catecholamines. The present work was undertaken to determine whether 5-hydroxytryptamine (found in the striatum of man in concentrations of about 0.5-1.0 µg/g<sup>10</sup>) is also influenced by a nigral lesion. The technique was the same as in our previous work: an electrolytic lesion was placed along the dorsomedial edge of the substantia nigra of seven monkeys with the aid of a stereotaxic instrument; lesions were made on the left side, the right side remaining untouched. After 108-126 days during which neurological observations were made, the animals were killed under deep 'Nembutal' anaesthesia, and the brains were removed. The caudate nucleus and putamen of each side were dissected, weighed and stored in the frozen state until the chemical analyses were performed. The remainder of the brain-stem was placed in 10 per cent neutral formalin, in preparation for histological examination. The parts of the brain to be analysed were homogenized in three parts of 0.1 N hydrochloric acid. Half this homogenate was then treated for determination of 5-hydroxytryptamine by the method of Bogdanski, Pletscher, Brodie and Udenfriend<sup>10</sup>. Dopamine was determined in the other half by the procedure of Sourkes and Murphy<sup>11</sup>, after extraction by the method of Shore and Ohm<sup>12</sup> for noradrenaline. Sections of the brain-stem were stained<sup>13</sup> and then examined to identify the site of the lesion and its effect, if any, on the cellularity of the substantia nigra. In this series, four of the seven monkeys showed a great loss of cells from the pars compacta on the operated side; the side opposite to the lesion had the usual degree of cellularity seen in sections taken from unoperated monkeys. This result is illustrated in Fig. 1.

A summary of the amine analyses is given in Table 1. It is evident that those animals that showed considerable loss of cells from the substantia nigra also lost much of the dopamine from the striatum of the same side; indeed, the loss amounted to 81-100 per cent of the dopamine, compared with the corresponding control structure. This, then, is in confirmation of earlier findings<sup>8,9</sup>. On the other hand, in those monkeys whose substantia nigra had a normal cellularity there was no difference between the striata of SP9 or between the caudate nuclei of SP1. The caudate nuclei of monkey SP2 and the putamenal nuclei of SP1 and SP2 showed large differences as between the operated and intact (control) sides, but these were not consistent in the direction of the differences.

In regard to the concentration of 5-hydroxytryptamine, the values for the nuclei of the operated side in the three animals retaining a normal complement of nigral cells (SP1, SP2 and SP9) ranged from 86 to 179 per cent of the values found in the corresponding parts on the intact side of the brain. The lower and higher extremes were found

Fig. 1. Transverse section through midbrain of monkey SP7 showing complete cell loss in the pars compacta of the substantia nigra on the side on which an electrolytic lesion had been made. The lesion, which interrupted the corresponding nigrostriatal fibres, was rostral to the level of the section shown

in the caudate nuclei of SP9 and SP1, respectively. Of the group of monkeys that had histological evidence of cellular loss on the operated side, SP8 had a greater concentration of 5-hydroxytryptamine on the operated side, but the others (SP7, SP10 and SP12) had 23-33 per cent less than in the corresponding parts of the intact side.

The concentration of dopamine in the brain has been previously shown to be sensitive to experimental lesions of the brain. Lesions of the substantia nigra cause a loss of dopamine from the striatum of the monkey, as determined by direct chemical analysis<sup>10,11</sup> or of the rat, as detected by a histological fluorescence technique<sup>12</sup>; lesions in the globus pallidus of the rabbit result in a decrease of dopamine of the caudate nucleus, beginning between the fourth and seventh days following operation<sup>13</sup>. These results are borne out by the results recorded here obtained with a new series of monkeys. It is noteworthy, however, that the changes in concentration of 5-hydroxytryptamine in the present series bear no obvious relation to those of dopamine. Of the four animals with nigral loss of cells resulting from the lesion, three showed a decrease in the 5-hydroxytryptamine concentration of the striatum on the operated side, but the fourth animal did not. This decrease was moderate (23-33 per cent), compared with the change in dopamine in the same structures or compared to the decrease in the concentration of 5-hydroxytryptamine seen in patients with Parkinson's disease (50-70 per cent)<sup>14</sup>. Thus, the amine changes following the nigral lesion are analogous to those observed in Parkinson's disease with respect to dopamine but, on the basis of the four monkeys in the present series that showed nigral loss of cells, the analogy cannot be extended to 5-hydroxytryptamine.

Table 1. DOPAMINE AND 5-HYDROXYTRYPTAMINE IN MONKEYS WITH UNILATERAL LESION OF THE BRAIN-STEM

Substantia nigra	No.	Structure	Dopamine*		5-Hydroxytryptamine*	
			Operated side	Intact side	Operated side	Intact side
Normal No. of cells on side of lesion	SP1	caudate	5.87	6.03	0.66	0.48
		putamen	2.38	6.28	0.99	1.00
	SP2	caudate	2.73	1.59	0.84	0.35
Decreased No. of cells on side of lesion	SP7	caudate	0.82	3.81	0.08	0.80
		putamen	0.40	3.53	0.56	0.77
	SP8	caudate	0.07	3.99	0.60	0.80
	SP10	caudate	0.94	4.30	0.30	0.58
		putamen	1.35	5.53	0.34	0.44
	SP12	caudate	0.96	3.02	0.30	0.54
		putamen	0.30	2.55	0.31	0.41

\* µg/g wet weight of tissue.

The influence, if any, of nigrostriatal fibres<sup>1</sup> on the concentration of this amine in the brain is being studied further.
